## 1. Introduction

### 1.1 General

Jacobs was commissioned by Transport Scotland to prepare a Design Manual for Roads and Bridges (DMRB) Stage 2 Assessment for the A9/A82 Longman Junction Assessment, and a DMRB Stage 3 Assessment for the A9/A96 Inshes to Smithton Scheme.

The transport modelling and economic appraisal work was undertaken using the Moray Firth Transport Model (MFTM) model. In preparation for these assessments, it was proposed that the MFTM base model be recalibrated and validated to reflect 2018 traffic conditions.

### 1.2 Report outline

This report provides details on the calibration and validation of the MFTM Base model, including changes to the model coding, matrix development and the level of calibration and validation achieved.

Chapter 2 outlines the general model specification;
Chapter 3 summarises the network and enhancements made for this update, and Chapter 4 covers the changes made to the Public Transport network. Revisions to observed matrices, including matrix estimation changes are given in Chapter 5 and the assignment model is discussed in Chapter 6. Calibration and validation results are given in Chapters 7 and 8 respectively. Chapter 9 summarises the development of the Demand model, which has not been altered during the update of the model, and finally a Summary and Conclusion has been included in Chapter 10.

## 2. Model Specification

### 2.1 Scope

The VISUM Model is a 4 Stage multi-modal model, including highway, bus and rail public transport networks. For the purposes of the model update, its focus is on Inverness city centre including Longman, Smithton and Inshes, which covers all major commuting catchments to the city and strategic movements from the rest of Scotland. The model also includes the settlements along the trunk road network as far north as Tain, south to Dalwhinnie, east to Granton on Spey and west of Garve, as shown in Figure 2-1.

Figure 2-1 Network Extents
The demand matrices include all traffic to, from, within and through the study area.
The MFTM 2014 Base model was developed in VISUM version 12.01-02, and this has since been updated to use version 17.01-04. It is supplemented by software scripts written in Python produced by the previous model developer ${ }^{1}$.

[^0]
### 2.2 Model years

The base model has been recalibrated to represent an average weekday in February 2018.

### 2.3 Time periods

The model has been developed for the following time periods:

- morning peak, 08:00-09:00;
- inter peak average hour, 10:00-16:00; and
- evening peak, 17:00-18:00.

### 2.4 Model zones and sectors

### 2.4.1 Extent of zone system

The model zone system remains consistent with that used in the previous version of the model with the exception of Zone 47, which covered Inverness Caledonian Football Stadium and the Landfill site to the east of the A9. This zone has been divided into two zones, moving the Landfill site into a separate zone, Zone 425. Separating this area into two zones allowed a better representation of traffic joining the network along this section of Stadium Road, which may be important when developing the future year models given the development aspirations in the area. Details of how the original zone system was developed can be found in Chapter 3 of the MFTM development report ${ }^{1}$. The zones representing Inverness and surrounding areas are shown in Figure 2-2 and for the rest of Scotland in Figure 2-3.

Figure 2-2: Zone system across Inverness

Figure 2-3: Zone system across Scotland

### 2.4.2 Sector System

To allow for further analysis and reporting as part of the model update, zones have been aggregated into 19 sectors. Sectors covering Inverness are shown in Figure 2-4 and the rest of Scotland are shown in Figure 2-5.

Figure 2-4 Sector system in the Inverness Area

Figure 2-5 Sectors system across Scotland

## 3. Highway Network Updates

### 3.1 Introduction

The original base model network was originally developed in 2009 and is detailed in the MFTM Development Report² (AECOM 2010), with the A96 corridor updated as part of the 2014 model update, detailed in the MFTM Base Model Update Calibration Report ${ }^{3}$ (Jacobs 2017). An extensive network review has since been undertaken, with a particular focus on Inverness City Centre including Longman, and the Smithton and Culloden area. This chapter summarises the key changes and updates implemented in the model networks.

### 3.2 Modelled Network

The most significant change to the road network between 2014 and 2018 within the study area is the opening of The Highland Councils West Link Phase 1 scheme, providing a new crossing of the River Ness to the southwest of Inverness. This section of the West Link Scheme opened in December 2017 and provides a connection from the A82 to Sir Walter Scott Drive.

The development of the network using ITN layers meant that very small residential streets were also imported. These were removed to reduce ambiguity within the model network. Due to the strategic nature of the model, the key consideration was the zone structure, and the points where the zones loaded onto the network. Upon reviewing the network, in conjunction with the zone loading points, areas of the road network were consolidated, removing a number of redundant links within the modelled area of Inverness.

### 3.3 Link Types

Link types were reviewed as part of the network checks, and a number were updated to better reflect road characteristics within the city centre. Figure 3-1 below and Table A-1 in Appendix A lists the links that have been subject to a change in Link Type.

Generally, the link type was changed to improve the consistency of link coding on the approach at the junction or to improve the consistency between coded link type and the quality and type of road that exists on the ground.

In the previous version of the model, the link coding on approach to junctions was inconsistent. In some instances, links were coded with the same link type as the rest of the route, meaning a speed flow curve was applied. In other instances, a short link was created on approach to the junction and a link type of 99 was applied, which does not have a speed flow curve applied, allowing the junction to control the speed on the link. The latter approach has now been applied throughout the immediate study area, where traffic on the link has to give way to an opposing traffic movement.

[^1]As mentioned above there were also instances where different link types had been applied to roads with similar attributes. This has been reviewed and the link types have been altered to make roads with similar attributes consistent.

In the case of Harbour Road, the link type was changed so a speed flow curve could be applied that meant the speeds would be closer to the observed speed. Harbour Road is a unique road within the model area as it has a large number of accesses to industrial units and car show rooms within a short stretch of road, meaning there is a significant amount of stop start traffic along the route with vehicles accessing various sites. In addition, it is common for car transporters to be stopped on the road, delivering vehicles to the showrooms, causing an obstruction to the traffic flow. The speed flow curve implemented on this link attempts to take account of these factors.

Figure 3-1 New Link Types

### 3.4 Link Capacities

The link capacities have been reviewed to assess how accurately they reflect current road conditions. As a result of this assessment, the capacities have been updated on a number of links. Figure 3-2 and Figure 3-3 show the link capacities originally coded and the updated capacities, for the links that have changed, respectively. Table A-2 in Appendix A lists the links where the capacity has been updated. The updated capacities are based on capacities used in the Transport Model for Scotland, aiming to provide consistency with other models within the LATIS suite.

Figure 3-2 Original Link Capacities

Figure 3-3 Updated Link Capacities

### 3.5 Free Flow Speed

Changes have been made to the free flow speed on a number of links. These changes have been implemented as the free flow speeds coded in the original base model did not accurately reflect the actual speed limit of the road or in some cases the achievable travel speed on a road based on observed data. For the links that have been modified, the original free flow speeds are shown in Figure 3-4, while Figure 3-5 shows the updated free flow speeds now coded in the model. A list of the key links has been included in Table A-3 in Appendix A.

Figure 3-4: Original free flow speeds

Figure 3-5 Updated free flow speeds

### 3.6 Junction Improvements

The signal times at Longman Roundabout have been updated to better reflect those observed on the ground. Journey time information approaching the junction was checked as part of the validation of the model and is report in Section 8.2 below. The junction coding was checked throughout the study area against Google Streetview to determine the correct control type and the major changes are included within Table A-4 in Appendix A.

### 3.7 Additional Links and Connectors

In addition to West Link to the southwest of Inverness, a number of minor links have been added to the model. The additional links were included to provide additional detail within the University of Highland and Island (UHI) Campus to reflect where traffic is originating within the campus. Other minor links have also been added to amend how a number of zones connect to the network. Originally, a number of Zone Connectors connected to a node in the middle of a link, this has been changed to create a junction with a short spigot link for the zone to connect to. The additional zone connectors or changes to the location of zone connectors are shown in Figure 3-6 to Figure 3-8.

Figure 3-6: Zone connector changes for Zones 123 and 114

Figure 3-7 Zone connector changes for Zones 47 and 425

Figure 3-8 Zone connector changes for Zones 128, 144 and 127

### 3.8 Link Penalties

Link Penalties have been introduced on two routes to represent perceived delay and to reflect observed route choice, to encourage traffic to route along Castlehill Road and Caulfield Road North. This has been applied to reflect local knowledge, where a proportion of local traffic avoids a potential queue on the Culloden Road approach to the Caulfield Road North signalised junction by routing via Castlehill Road and Caulfield Road North.

### 3.9 Network Summary Statistics

Table 3-1 summarises the number of elements for each of the different components of the high-level model.

## Table 3-1 : Network summary statistics

| Element | Number |
| :--- | :--- |
| Network nodes | 10,128 |
| Network links | 23,134 |
| Demand zones | 441 |
| Zone Connectors | 3,384 |
| Rail stations | 4 |
| Bus stops | 1,247 |

## 4. Public Transport Updates

### 4.1 Introduction

In addition to the model network review, the public transport network was also reviewed to include updated bus services and to remove out-of-date services. Similar to the model network, particular attention was paid to Inverness City Centre and long-distance bus routes that originate in, terminate in or pass through Inverness. This chapter summarises the key changes and updates implemented for Public Transport.

### 4.2 Lines and Route Lines

In order to determine the out-of-date bus services within the public transport network, an online search of bus services operating within Inverness City Centre, and the wider area, was undertaken using the operators' websites. In addition, the Bus Route Lines attribute tool on Basemap DataCutter was employed as a database in ArcGIS to identify every bus service number operating within the Highland area. The services that yielded no results across the operators' websites and within the Bus Route Lines database were subsequently deleted from the model, as this is indicative that they are no longer in operation. Once the out-of-date services were removed from the model, the existing bus stops in Inverness City Centre were checked using Basemap's multi-modal transport tool, TRACC. Any missing bus stops were added to the network, and any redundant bus stops in the model were removed.

Analysis of the remaining bus service routes in the public transport network was undertaken using the DataCutter Bus Line Routes shapefile in ArcGIS. This demonstrated the first departure bus stop location and the final arrival bus stop location, and therefore the complete line route for each service. Existing lines containing the complete routes were copied and edited in VISUM to demonstrate all the line routes for each service; approximately 40 existing bus line routes were edited, as per the operators' timetable and bus stop locations. In addition, new bus services were identified across the region using the DataCutter Bus Line database. Over 30 new bus lines were coded into the public transport network using the bus line tools in VISUM. To this end, the Base Model, Do Minimum Model and Do Something Model consist of 177 bus line routes.

### 4.3 Timetables

A number of bus services offer variations of routes throughout the three peak periods; that is a service number will remain the same, but it may start or terminate at a different location in the AM peak compared to the PM peak. This was not evident from the Bus Line Route Shapefile obtained from DataCutter, therefore, a variety of data sources were used to identify and add the bus timetables for each service throughout the three peak periods; this information was derived from the multi-modal transport tool TRACC and the operators' timetable sections on their websites.

### 4.4 Network and Service Validation

The transit tool in Google Maps was employed to validate the bus service numbers and bus stop locations in relation to the departure and arrival points of each new and existing bus service within the public transport network. In addition, new and existing bus service timetables and line routes across the three peak periods were validated using the interactive timetable tool and map on Travelinescotland.com. Observed Matrix Development

### 4.5 New Count Data

The model update has been targeted to improve the quality of the model and to ensure it best represents the area of Inverness in 2018. To achieve this, a data collection exercise was agreed with Transport Scotland and undertaken in February 2018. This consisted of surveying 24 ATC sites and 20 JTC sites within the city centre shown in Figure 4-1 and Figure 4-2 and a selection of the new count data was used during the matrix estimation process as calibration counts. The remaining count information was kept independent of the data utilised during Matrix Estimation and was retained for model validation purposes. The sites marked with a red circle in Figure 4-1 and Figure 4-2 have been used in calibration, those marked with a blue star were kept independent for validation. Transport Scotland and The Highland Council maintain permanent ATC counters situated around Inverness and on the trunk road network, including the A96, these counts were also utilised in the calibration and validation process, shown in Figure 4-3.

Figure 4-1 ATC and JTC Locations - South of Inverness and City Centre

Figure 4-2 ATC and JTC Locations - City Centre and Longman Junction

Figure 4-3 Transport Scotland and The Highland Council Permanent Sites

Figure 4-4 Roadside Interview Locations (June 2018)

### 4.6 Prior Matrix Development

As part of the MFTM base model update, it was determined that the prior matrices used for the original base model should be reviewed and updated where possible. A range of data sources were collected to inform the overall process of producing updated observed prior matrices. These were as follow:

- Business Registered and Employment Survey (BRES) Data;
- Census Population and Housing Data;
- Census Travel to Work Data (at a 2011 Data Zone Level);
- Scottish Household Survey Data; and
- Roadside Interview (RSI) Data (2006-2010).

As detailed in section 5.3, RSI surveys were also undertaken in June 2018, with the data received in July 2018. The data was not available at the time the prior matrices were being
developed and was therefore used to validate the trip patterns within the matrices. From the remaining datasets, only the Car Commute prior matrix could be updated as no information was available to update the Car Other Matrix or the Car In Work Matrix.

The Census Travel to work data was used as the basis for the Car Commute Matrix. This data is based on the 2011 Census and is provided at 2011 Data Zone level. It was subsequently converted into the MFTM zone structure based on proportions derived from overlaying the 2011 data zones with the model zones to determine the area of each data zone that would fall within the boundary of each model zone. As the Census Travel to work data surveys how each person travels to work, this had to be converted into vehicle trips. Car occupancy factors obtained from the WebTAG Databook (December 2017)4 were used to further condense the matrix so that it represented commuting trips across a 24-hour period.

Table 5.1: Peak Period Occupancy Factors

| Peak Period | Factor |
| :--- | :--- |
| AM Peak | 1.17 |
| PM Peak | 1.16 |

As the travel to work data covers a 24 -hour period, there was a requirement to reduce the matrix to reflect a 12 -hour period to coincide with the available RSI data. To take account of this, the percentage of shift workers were removed to establish the number of people who travel between 0700 and 1900. The Office of National Statistics records indicates that the number of individuals undertaking shift work within the United Kingdom is approximately $22 \%$. It has been assumed that shift workers will not travel within the peak periods, and that by reducing the 24 -hour travel to work matrix by $22 \%$, the remaining commuters will be those that travel between 0700 and 1900.

To reduce the matrix to peak level, historic RSI data was used to calculate the number of commuting trips that occurred within the peak periods. These factors were based on the number of interviews held between a peak-hour specifically for commuting trips by car or taxi. The following factors were applied:

Table 5.1: Peak Period Factors

| Peak Period | Factor |
| :--- | :--- |
| AM Peak | 0.37 |
| Inter Peak | 0.07 |
| PM Peak | 0.25 |

As the travel to work data was recorded in 2011, a factor was derived to apply growth to 2017. The permanent ATC data within the model are was analysed and a growth factor of 1.02 was applied to the data uplift the matrix to 2017 levels, as the last full year of data available at the time of the matrix development.

[^2]As data was unavailable for other vehicles classes, the existing 2009 prior matrices for Car In Work, Car Other, LGV and HGV were used. Matrices from the TMfS cordon models of Inverness and surrounding areas were used to calculate the growth between 2009 and 2017. The prior trips-ends were then multiplied but the resultant growth factors to uplift each matrix to a 2017 base year. Table 5.2 shows the percentage increase applied to matrix:

Table 5.2: Growth Applied to Prior Matrices

| Prior Matrix | Percentage Growth for 2009-2017 |  |  |
| :--- | :---: | :---: | :---: |
|  | AM Peak | Inter Peak | PM Peak |
| Car in Work | $5.7 \%$ | $4.2 \%$ | $5.8 \%$ |
| Car Other | $9.5 \%$ | $10.2 \%$ | $11.7 \%$ |
| LGV | $29.2 \%$ | $29 \%$ | $27.1 \%$ |
| HGV | $19.3 \%$ | $18.3 \%$ | $18.6 \%$ |

### 4.6.1 Matrix Modifications

As the travel to work data was provided at datazone level and disaggregated to the MFTM zones based on area, it was necessary to make certain modifications to the final prior matrices to better reflect the land use across Inverness. In addition, the Car In Work, Car Other, LGV and HGV prior matrices were based on the original 2009 MFTM prior matrices. Since 2009, there has been a change to the land use in certain zones, which will alter the trip generators and attractors within the area, so modifications to the prior matrices were necessary. The modifications applied varied from site to site but generally the redistribution of trips was based on the number of households and jobs

### 4.6.1.1 University of Highlands and Islands

The University of Highlands and Islands Campus relocated from a site to the west of Longman Road to a new site to the west of Cradlehall Business Park in 2016, therefore, the number of trips originating and terminating within the new UHI zone (zone 123) required adjustment based on a review of the traffic count data travelling through several junctions adjacent to the campus. A junction turning count was undertaken at the main entrance to the site which allowed the number of trips travelling via this access to be determined. However, there was no count information available for the secondary access. To establish the level of trips access and egressing via the secondary access, count information was taken from JTC 14, located at the Caulfield Road North/Culloden Road Junction, and ATC 23 and 24 which are located on Castlehill Road and Caulfield Road, respectively. A flow bundle was undertaken to determine the origin of the additional trips, allowing the distribution of traffic accessing the campus via Caulfield Road and Castlehill Road to be determined and added to the Car Other matrix.

### 4.6.1.2 Cradlehall Primary School

The ATC on Caulfield Road (ATC 24) indicated that the modelled traffic volumes passing Cradlehall Primary School were considerably lower than observed. Consideration was given to why vehicles would travel along this route as the most obvious route to Culloden Road is to continue South on Tower Road. One of the main reasons for using Caulfield Road would
be to drop children off at the primary school in the AM peak. The number of trips travelling to Zone 119, which contains Cradlehall Primary School, was lower than would be expected for a school of that size. The Trip Rate Information Computer System (TRICS) was used to determine a likely trip rate for Cradlehall Primary School based on the school roll and the additional trips added to the matrix, and distributed across zones 117, 196, 195, 116, 115, 106, 120, 121 and 122 which represent the school catchment area.

### 4.6.1.3 Raigmore Hospital

Following an initial run of matrix estimation, traffic flows entering and exiting Raigmore Hospital were compared to traffic counts undertaken in 2014 as this was the most up to date data source available. As this count was collected in 2014, a check was undertaken using the ATCs within the model area to determine the level of growth between 2014 and 2017, as the last full year of data. This indicated that there was no growth within the area, and as such, the 2014 count information was considered a reasonable data source to determine the number of trips travelling to and from both the Raigmore Hospital (Zone 197) and the residential area adjacent to the hospital (Zone 198), as these area share an access.

Comparing the modelled flows with the 2014 turning count information indicated that the level of traffic accessing and egressing the zones were considerably higher than anticipated, resulting in higher than anticipated traffic volumes along the Culloden Road corridor. To rectify this, a percentage reduction was calculated based on the number of trips accessing and egressing the zones in the model compared with the observed 2014 traffic count. The number of trips travelling to Raigmore Hospital were therefore reduced by approximately $40 \%$ in the AM Peak, and trips from both Raigmore Hospital and the residential zones were reduced by approximately $60 \%$ in the PM Peak.

As mentioned in Section 5.2, during the development of the Car Commute Matrix, shift work was taken account of by applying a factor to the entire matrix based on national averages. A significantly higher number of employees at Raigmore Hospital are likely to work shifts than the national average, which may therefore explain why the level of trips to and from the hospital zone were higher than those observed in 2014.

### 4.6.1.4 Inshes Retail Park

Matrix adjustments were made to trips originating from zone 107, which represents Inshes Retail Park and Tesco Extra. The travel to work data, used to generate the Car Commute Prior Matrix, would not capture multi-leg journeys as the travel to work data only details where each person lives and works. Zones that contain amenities such as Inshes Retail Park are likely to attract multi-leg journeys and will therefore have a proportion of trips that use this as an intermediate stop within the peak hour model. This zone was highlighted as an issue following a comparison of modelled and observed flows at Inshes Roundabout and on Sir Walter Scott Drive. Modelled and observed flows compared relatively well to on Sir Walter Scott Drive to the south of Eagle Roundabout. This changed on approach to Inshes Roundabout, where the Sir Walter Scott Drive approach in the model was approximately 200 vehicles higher than observed, and the arm approaching Inshes from Tesco was 200 vehicles lower than observed. This indicated there were some multi-leg journeys entering Inshes Retail Park at The Eagle Roundabout before exiting at Inshes Roundabout.

To replicate these multi-leg journeys, approximately 200 trips, that were previously approaching Inshes roundabout from Sir Walter Scott Drive were relocated to have a destination in the Inshes Retail Park, exiting Sir Walter Scott Drive at The Eagle Roundabout. The same number of trips were then added to the origins of Inshes Retail Park, exiting via Inshes Roundabout and terminating at their original destinations. A flow bundle matrix for each user class was used to establish the distribution of trips approaching Inshes Roundabout from Sir Walter Scott Drive and this was used to redistribute trips to the Inshes Retail Park.

### 4.6.1.5 Seafield Road

The count data on the A82 Longman Road indicated that approximately 200 trips turned left from Seafield Road and made a U-turn at Harbour Road roundabout in order to approach Longman Junction from the southwest. As matrix estimation was undertaken using link flows as targets and not turns, the high U-Turn value was not being taken account of. A flow bundle matrix was calculated for vehicles that travel on Seafield Road to determine the distribution of trips and allow the number of trips travelling towards Longman Junction to be increased to match the count information.

### 4.6.1.6 Inverness Retail and Business Park

The level of trips travelling to and from Seafield Retail Park is relatively low in the AM Peak. As the majority of these trips are Car Other trips, the trip totals would have been brought forward from the 2009 base model matrices. A review of the 2014 base model showed that there was a significant increase in trips travelling to and from this zone when the model was recalibrated in 2014, with a similar turning pattern to those observed in the JTC undertaken in February 2018. The trip pattern was therefore extracted from the 2014 matrix and added to the 2009 prior matrix.

### 4.6.1.7 Ashton Farm

Zone 127 encompasses Ashton Farm in the model. As this zone only contains Ashton Farm, it is not anticipated to generate or attract a significant number of trips. As a result of the way the travel to work information was disaggregated, the number of car commute trips travelling to and from Zone 127 is larger than expected, particularly in the PM Peak. A manual change has been applied to relocate these trips into Zones 121 and 122, which represent a residential zone and business park and residential zone respectively. As this was the PM Peak, the origin information was transferred into the business park zone, with the destination trips transferred into both zones based on a $50 / 50$ split as both zones contain residential dwellings.

### 4.6.1.8 Light and Heavy Good Vehicles

Generally, the LGV and HGV prior matrices were not changed from the 2009 model as there was no data available to update these. However, there were certain zones where the land use had changed, or the available count information indicated that the number of LGVs and HGVs entering or exiting a zone were lower than observed. The two zones that were impacted by this change are Zone 35, which represents Longman Industrial Estate, and Zone 123 which represents the UHI Campus.

The number of LGVs entering and exiting Zone 35 were considerably lower than the observed counts, and considerably lower than what would be expected from an industrial estate of this size. The origin and destination numbers were increased to match the available count information and the distribution seeded, changing all of the zeros to 0.1 to allow Matrix Estimation some flexibility in meeting the count information.

As the land use of Zone 123 was a greenfield site in 2009 the level of LGVs and HGVs travelling to and from this zone were zero. This site is now the location of the UHI, and the level of LGVs and HGVs travelling to and from the site via the main access are known based on count information. This count was used to determine the correct level of goods vehicles, and a distribution was taken from a neighbouring zone, zone 124, which is the Inverness Retail and Business Park.

### 4.6.1.9 Public Transport

A review of the available data from the Scottish Transport Statistics ${ }^{5}$ indicated that bus patronage within the Highland region has remained consistent between 2009 and 2017, with a slight reduction occurring in 2017. As a result of this, and a lack of available data to update the matrix, the public transport matrix remained unchanged from the original 2009 base model.

### 4.7 Prior Matrix Validation

Roadside Interview (RSI) Surveys were conducted in June 2018 at five locations, as shown in Figure 5-4. This information was used to validate the sector to sector movements of the matrices, as a check that the travel patterns hadn't significantly changed from the 2009 model, particularly for the Car Other and Car In Work matrices as the Car Commute matrices have been updated in the process using the travel to work data. The analysis has been undertaken based on the sector system identified in Figure 2-4 and Figure 2-5. As the RSI locations were chosen to capture the trips into the detailed model area, this does mean that portions of the matrix were not captured by the RSI survey data. The trips that are likely to pass through the areas of interest have been captured by the RSI surveys, hence this data can be used to validate the matrix. To replicate the trip patterns that would be captured by the RSI, a filter matrix was created by undertaking flow bundle on the links that correspond to the RSI locations. This allowed all sector to sector movements that would not pass through the RSI sites to be filtered out of the prior and estimated matrices, before comparison with the RSI matrix.

A comparison between the sector to sector movements for Car In Work, Car Commute, Car Other and LGV has been undertaken and the distribution tables are available in Appendix B. A summary of the comparison for each journey purpose in each peak is detailed below.

[^3]

Figure 4-5 Roadside Interview Locations (June 2018)

### 4.7.1 AM Peak

The RSI surveys indicate that the majority of trips are travelling to Sector 16 in the AM Peak for Car In work, Car Commute and Car Other trips, which represents the area around Inshes and the City Centre to the south of the Railway. This compares well with the prior matrices where the main concentration of destinations in Sector 16.

Sector 15 and 19 have the second highest level of trip attractions in the prior matrices. Sector 15 represents the area of Inverness North of the Railway, including Longman Industrial Estate, the Longman Landfill site and Inverness Caledonian Football Stadium and Sector 19 encompasses the areas of Merkinch, South Kessock and Dalneigh, which are a mixture of residential and employment zones, including where The Highland Council's Headquarters are situated. It is evident from the Car Commute RSI matrices that both of these sectors also have a degree of trips attracted to them in the AM Peak. Whilst the Car In Work and Car Other RSI matrices show a degree of correlation with the prior matrices, they do not contain the same level of observed trips as the Car Commute matrix. With the lower levels of Car In Work and Car Other purposes observed from the RSIs, it is more difficult to discern patterns from the RSI matrix and draw comparisons with the prior matrices.

Similarly, the distribution of the prior matrix indicates that Sector 17 is also an attractor of trips from most sectors, albeit a low concentration of trips. This is somewhat evident from the RSI matrices, where Sector 17 is an attractor of trips from some sectors, however the distribution is not as widespread in the RSI information as it is within the prior matrices. This is most likely a result of the sample rate obtained from the RSI. Sector 17 is a likely attractor of trips from a broad range of sectors in the AM Peak as the UHI Campus is located here, and trips have been infilled to this site during the matrix building process based on count information and the prior matrix is therefore considered to be valid.

The available RSI information for LGVs is quite limited with only 54 trips recorded across the four sites. This makes comparison with the prior matrix difficult, however it does indicate a similar pattern to the Car matrices, with large percentages of trips travelling to Sectors 15, 16 and 19.

The rest of the matrices are populated with small percentages between sectors, and this is to be expected as the sample size of the RSI is small and not all trips can be observed.
Generally speaking, the RSI replicates the larger sector to sector movements in the AM Peak and indicate that the prior matrices are a valid representation of the trip distribution in the area.

### 4.7.2 Inter Peak

The Inter Peak RIS matrices show a similar pattern to the AM Peak, which is primarily due to the locations of the RSIs capturing trips entering Inverness. As in the AM Peak, the travel patterns identified within the RSI surveys is similar to those identified within the prior matrices, with the highest proportion of trips travelling to Sector 16, followed by 15, 17 and 19. The correlation between sector to sector travel patterns in the RSI and Prior matrices is particularly strong for the Car Commute journey purpose.

As with the AM Peak, the data does indicate that the sector to sector movements in the prior matrices are valid and a reflect of the RSI.

### 4.7.3 PM Peak

As the RSI is inbound towards Inverness, the survey does not observe the dominant direction of travel, and the sample rates are slightly lower. This is particularly evident for the Car Commute and Car In Work journey purposes where the observed RSI matrices are sparsely populated, compared to the prior matrices. The do however show a degree of correlation in so far as where observed data was available, the prior matrices showed trips travelling between these sectors. The Car Other matrices has a slightly higher level of observed trips and this again shows a reasonable correlation between the observed data and the Prior matrices.

The dominant movements in the PM Peak are leaving Inverness which has not been captured by the RSI. However, from the available data, the Prior matrices are a reasonable representation of the available observed data.

### 4.8 Matrix Estimation

In updating the model, the prior matrices have been adjusted by matrix estimation using new count data.

In many modelling packages, the matrix estimation methods employed rely on multiple factoring of a matrix until a solution is derived. Factoring is undertaken in series and because many of the values in the matrix are affected by multiple control counts, the process has to be repeated iteratively until a suitable correlation is found for all the counts. Inevitably, this means that those trips that are affected by fewer control counts (usually the shorter trips) are subject to more extreme aggregate factors and this consequently distorts the trip distribution.

The matrix estimation process in VISUM (TFlowFuzzy) is more complex; it attempts to find suitable factors by considering all control counts simultaneously. The most noticeable advantage of this is that the trip distribution is maintained, whilst still producing a good correlation between the count data and predicted flows.

Due to the available of count data, it was required to combine the three car journey purpose matrices into one and assigned to the network prior to undertaking matrix estimation. The resultant matrix was then divided into journey purpose based on the percentage split of the car prior matrix.

The initial pass of matrix estimation indicated that the car matrix was too high for the observed data, meaning TFlowFuzzy terminated as it couldn't match the counts within the tolerances allowed. As the Car Other and Car In Work matrices were similar to those used in the previous base models, and the Car Commute matrix was created by applying factors to the Travel to Work data, it indicated that the Car Commute matrix was too high. Two tests were therefore undertaken, one reducing the matrix by $10 \%$ and another by $20 \%$ to determine the reduction required to allow TFlowFuzzy to run. The 20\% reduction allowed TFlowFuzzy to run, and as the matrix was reduced further by the matrix estimation process, undertaking tests to apply a reduction lower than $20 \%$ were deemed unnecessary.

### 4.9 Matrix changes

### 4.9.1 Change in matrix totals

Table 4-1 indicates the change in the Car, LGV and HGV matrix totals, which occurred during the matrix estimation process for the AM Peak. Matrix totals for the Inter Peak and PM Peak are included in Table 4-2 and Table 4-3 respectively.

Table 4-1: $\quad$ Matrix totals AM Peak

|  | Car <br> Commute | Car In Work | Car Non <br> Work | LGV | HGV |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Pre ME | 16,798 | 1,564 | 4,277 | 1,860 | 931 |
| Post ME | 14,814 | 1,470 | 4,455 | 2,083 | 667 |
| Percentage <br> Change | $-12 \%$ | $-6 \%$ | $4 \%$ | $12 \%$ | $-28 \%$ |

Table 4-2: Matrix totals Inter Peak

|  | Car <br> Commute | Car In Work | Car Non <br> Work | LGV | HGV |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Pre ME | 4592 | 1124 | 11169 | 1379 | 1228 |
| Post ME | 6580 | 1478 | 14230 | 1777 | 718 |
| Percentage <br> Change | $43 \%$ | $31 \%$ | $27 \%$ | $29 \%$ | $-42 \%$ |

Table 4-3: $\quad$ Matrix totals PM Peak

|  | Car <br> Commute | Car In Work | Car Non <br> Work | LGV | HGV |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Pre ME | 12,277 | 1,326 | 10,265 | 1,229 | 280 |
| Post ME | 10,969 | 1,169 | 9,516 | 1,737 | 311 |
| Percentage <br> Change | $-11 \%$ | $-12 \%$ | $-7 \%$ | $41 \%$ | $11 \%$ |

### 4.9.2 Change in Zone to Zone demands

Figure 4-6 to Figure 4-8 show the change in zone to zone trip ends for All Vehicles.
Generally, they show a good correlation between pre and post matrix estimation sector totals. It is acknowledged that they are not fully informative as they do not show the relative importance of individual zones. Overall, the zone to zone trip ends are deemed acceptable as the $R^{2}$ values are at or approach WebTAG guidance of $R^{2}$ in excess of 0.95 . The cell to cell values have also been compared and the $R^{2}$ values are slightly lower in the Inter Peak and PM Peak, however, are still approaching 0.90 .

The slope is low across the AM and PM peak graphs, at around 0.90 , this indicates that the size of the matrix decreases between the prior and post ME values. This is most likely a result of the Car Commute prior matrix being high as it was based on factoring the travel to work data.

The slope of the Inter Peak graph is higher at between 2 and 2.5, indicating a large number of trips have been added into the Inter Peak matrices during matrix estimation. This again could be linked to the Car Commute matrix, as the factor for the number of commuting trips was low, and the Car Commuting matrix has the largest percentage increase of all vehicles. Overall, the results are deemed acceptable given the $\mathrm{R}^{2}$ values.

Table 4-4: $\quad$ Zone to Zone Slope, $\mathbf{R}^{2}$ and Intercept Values

|  | WebTAG <br> Criteria | AM | IP | PM |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Zone to Zone <br> Values Slope | $0.98><1.02$ | 0.85 | 2.26 | 0.88 |
| Zone Trip Ends Slope | $0.99><1.01$ | 0.91 | 2.47 | 0.92 |
| Zone to Zone Cell <br> Values R |  |  |  |  |
| Zone Trip Ends R |  |  |  |  |
| values | $>0.95$ | 0.96 | 0.89 | 0.86 |
| Zone to Zone Cell <br> Values Intercept | $>0.98$ | 0.95 | 0.94 | 0.96 |
| Zone Trip Ends <br> Intercept | Near 0 | -0.01 | 0.02 | 0.01 |

Figure 4-6: Comparison of pre and post-ME total demand (AM peak)

Figure 4-7: Comparison of pre and post-ME total demand (Inter Peak)

Figure 4-8: Comparison of pre and post-ME total demand (PM peak)

### 4.9.3 Change in trip length distribution

Figure 4-9 to Figure 4-11 illustrates the pre and post-estimation for All Vehicles trip length distributions; it shows that the matrix estimation process has maintained the existing trip length distribution across the AM and PM Peaks. The Inter Peak trip length distribution has an increase in the number of trips between 3 km and 5 km , with a reduction in the longer distance trips greater than 10kms. The RSIs used to validate the matrix were undertaken on the periphery of Inverness, and therefore observed longer distance trips. A similar issue occurred when the Inter Peak model was rebased in 2014, and as there was limited observed data was available to inform the prior matrices or adjust the trip length distribution, matrix estimation has added shorter distance trips into the matrix to meet to observed link count data.

WebTAG criteria states that the mean trip length distribution and the standard deviation of the trip length distribution should not change by more the $5 \%$ pre and post matrix estimation. The values for each peak and shown in Table 4-5, Table 4-6 and Table 4-7.

Table 4-5 Mean Trip Length Distribution and Standard Deviation Percentage Changes - AM Peak

|  | All Veh | Car | LGV | HGV |
| :---: | :---: | :---: | :---: | :---: |
| \% Change in Mean Trip <br> Length Distribution | $-7 \%$ | $-9 \%$ | $1 \%$ | $3 \%$ |
| \% Change in Standard <br> Deviation | $-4 \%$ | $-5 \%$ | $9 \%$ | $10 \%$ |

Table 4-6 Mean Trip Length Distribution and Standard Deviation Percentage Changes - Inter Peak

|  | All Veh | Car | LGV | HGV |
| :--- | ---: | ---: | ---: | ---: |
| \% Change in Mean Trip <br> Length Distribution | $-20 \%$ | $-22 \%$ | $31 \%$ | $-34 \%$ |
| \% Change in Standard <br> Deviation | $-11 \%$ | $-13 \%$ | $24 \%$ | $-28 \%$ |

Table 4-7 Mean Trip Length Distribution and Standard Deviation Percentage Changes - PM Peak

|  | All Veh | Car | LGV | HGV |
| :--- | ---: | ---: | ---: | ---: |
| \% Change in Mean Trip <br> Length Distribution | $-2 \%$ | $-6 \%$ | $3 \%$ | $-7 \%$ |
| \% Change in Standard <br> Deviation | $-2 \%$ | $-3 \%$ | $11 \%$ | $-15 \%$ |

As shown in the tables above, for All Vehicles the percentage change in the mean trip length distribution and standard deviation is below, or close to, the 5\% threshold in the AM and PM Peaks. The Inter Peak has a higher percentage change, and this is a function of Matrix Estimation inserting shorter distance trips as discussed above. Disaggregating this further into vehicles classes, generally a similar pattern is prevalent, where the percentage change of mean trip length is around 5\% for the AM and PM Peak and the change in standard
deviation meets the $5 \%$ criterion for Cars and is slightly higher for LGV and HGVs, where there is less observed data available. As with All Vehicles, the Inter Peak values are higher than the other time periods, however Matrix Estimation was required to increase the number of trips significantly in the Inter Peak due to a lack of observed data being available, so this is somewhat expected.

Overall, the matrix estimation process has not significantly changed the size and shape of the matrices. The trip length distributions for the updated model closely match the prior and original model distributions and the results are therefore considered to be acceptable.

Figure 4-9: Comparison of pre and post-ME trip length distributions (AM peak, All Vehicles)

Figure 4-10: Comparison of pre and post-ME trip length distributions (Inter Peak, All Vehicles)

Figure 4-11: Comparison of pre- and post-ME trip length distributions (PM peak, All Vehicles)

### 4.10 Sectored matrices

### 4.10.1 Pre and post matrix estimation comparison

Figure 4-12 and Figure 4-13 illustrate the model sector system. A locational description of the sectors is included in Table 4-8.

Figure 4-12 Sector system in the Inverness Area

Figure 4-13 Sectors system across Scotland

Table 4-8: Sector locations

| Zone | Location | Zone | Location |
| :--- | :--- | :--- | :--- |
| 1 | A96 corridor to Nairn | 11 | Far north of Scotland |
| 2 | South Highland | 12 | Loch Fannich \& Luichart |
| 3 | Rest of Scotland \& UK | 13 | Grantown-on-Spey \& surrounding <br> area |
| 4 | Central West Highland | 14 | Inverness south |
| 5 | North east Scotland | 15 | Inverness north |
| 6 | Eastern Black Isle | 16 | Inverness central |
| 7 | Central Highland | 17 | UHI \& Seafield retail park |
| 8 | East of Westhill | 18 | Western Black Isle |
| 9 | Nairn \& surrounding area | 19 | Inverness west |
| 10 | Inverness station car park |  |  |

The change in matrix sector to sector travel demand between pre and post matrix estimation is summarised by percentage change compared to the prior matrix for all traffic in Table 4-9, Table 5-11 and Table 5-13 for the AM Peak, Inter Peak and PM Peak periods respectively. WebTAG states in Table 5 of Unit 3.16 that the sector to sector differences should be within $5 \%$. The comparison shows the majority of sectors change by more than $5 \%$ across all peaks, as shown by the red values in Table 4-9, Table 4-11 and Table 4-13 below, however the majority of these sector to sector movements show an absolute change less than 50 as shown in Table 4-10, Table 4-12 and Table 4-14. The sector to sector movements that have a larger absolute change than 50 vehicles are highlighted in yellow.

From Table 4-9 there are a number of internal sector movements that have between an 8\% and $15 \%$ change when compared to the prior matrix. Sector 3, 11 and 18 are outwith the area of interest and area where detailed count information was included for matrix estimation, as these represent the Rest of Scotland south of Inverness, the North of Scotland, and the western Black Isle areas respectively, and as such the changes to internal sector to sector movements within these sectors are not of particular concern. Sector 19 (Inverness West) is situated in Inverness to the west of the River Ness and whilst within the study area, the count data controlling the matrix estimation was not focused on this area and it is not anticipated that the model will be used to test any schemes within the sector, therefore an internal sector change of 80 vehicles (15\%) is deemed inconsequential.

Sector 16 is situated in Southern Inverness with a number of control counts in the area. This intra sector change within this sector is marginally higher than the acceptable $5 \%$ level of change stated in the guidance however, an increase of an additional 3\% represents less than 30 vehicles in a sector that contains a large number of housing, employment and retail facilities, and as such is considered acceptable.

There is a significant increase in the number of trips travelling from Sector 15 (Inverness North) to Sector 16 (Inverness Central), with an increase 156 vehicles (177\%) following the Matrix Estimation process. This is the largest change in both absolute values and percentage change in the AM Peak. This sector to sector movement is within the RSI cordon so would not be observed by the surveys. As mentioned in Section 5.2, the Car Commute matrix is the only matrix that has been updated with revised observed data obtained via the 2011 Census Travel to Work data, and this user class shows only a slight increase in the level of trips, at approximately 35 vehicles. Due to a lack of data for the other four journey purpose matrices, the matrices have had growth applied to them, however the origin and destination pattern remained the same as the original base model developed in 2009. The RSI information that informed the original matrix development did not capture the movements between these two sectors, and therefore is less robust than other areas of the 2018 prior matrix that have been validated by observed data. As such, the growth between these two sectors is considered acceptable as this is predominantly increasing trips on the local road network to match count data, in a sector to sector movement that has not been validated by observed data.

The remaining changes of note are between Sector 1 (A96 Corridor) and Sectors 15 (Inverness North), 16 (Inverness Central) and 17 (UHI and Seafield Retail Park). Trips originating in Sector 1 and travelling to Sectors 15 and 16 have been reduced by matrix estimation, whilst the number of journeys travelling to Sector 17 have increased. The increase in the number of trips travelling to Sector 17 is most likely due the development of the UHI campus, which has occurred since the 2009 model was originally developed. This may be attracting some trips that would have previously been travelling to the centre of Inverness, particularly Sector 15, where the UHI Campus was originally located. The changes between these sectors have therefore been deemed acceptable due to the change in land use and development that has occurred since the majority of the matrices were developed.

Generally, the pattern of the remaining significant changes shows a reduction of sector to sector trips, which is consistent with what has been mentioned earlier in this report, where by the Car Commute prior matrix was considered to be slightly higher than required.

Table 4-11 shows that, whilst the percentage change is above the threshold set in WebTAG, the majority of the changes are less the 50 vehicles. The Inter Peak matrix has the most significant changes of all three peak periods when compared to the prior matrix, however a large proportion of the differences are intra sector movements, and the remaining changes that are over 50 vehicles show a similar pattern to a combination of the AM and PM peak changes.

As in the AM Peak, the vast majority of the intra sector movements are outwith the core area of the schemes that this model will be used to assess. Sectors 14, 15, and 16 lie within the core area and are being controlled by the count data as part of matrix estimation.

As there was a lack of observed data for the main Inter Peak journey purposes, the prior matrices were taken from the 2009 base model, and growth was applied to increase the matrix values to a 2018 level. Whilst some changes were made to the prior matrices to take account of land use changes, matrix estimation had to add additional trips into the matrix to bring the matrix values to the level required to meet the count data. As the majority of the count information is located within Sectors 14,15 and 16, matrix estimation has increased the number of trips traveling to, from and within these sectors, which explains why there is a significant change in the number of trips travelling between sectors 14,15 and 16. Overall, it is felt that the changes to the matrix are acceptable as the traffic volumes within the vicinity of the schemes that this model will be used for are generally correct.

Table 4-13 shows that, whilst based on a percentage change a large number of sector to sector movements are above the threshold set in WebTAG, the majority of the changes are less the 50 vehicles, and therefore, generally the PM Peak estimated matrix compares well with the prior. As in the AM Peak, the intra sector movements at Sectors 3, 11, 18 and 19 are not of major concern as these are outwith the area of influence of the model.

The majority of the significant changes are originating from Sector 16, and these are all showing a reduction when compared to the prior matrix. This sector has significantly more origin trips in the PM Peak than any other sector in the prior matrix, mainly due to the large employment areas around Raigmore Hospital. As a result, Matrix Estimation has removed a larger number of trips from this sector, compared to the others when reducing the overall matrix totals to meet the observed count information. The total number of trips originating in Sector 16 remains a similar proportion of the total matrix pre and post estimation and this is therefore deemed acceptable.

The other sector to sector movements of note are Sector 15 (Inverness North) to Sector 17 (UHI and Seafield Retail Park), and to Sector 19 (Inverness West), which have a change of 104 and 110 vehicles respectively. The majority of the reduction in trips travelling between Sector 15 and 17 are Car Other trips. As mentioned previously this matrix was not updated with new observed data, there is therefore less confidence in the trip patterns of this matrix. Of the trips originating from Sector 15, trips to Sector 17 reduces from $11 \%$ to $8 \%$, which remains a significant percentage of trips from this sector. It is believed that this change is acceptable as the level of trips making this movement post estimation continues to be significant. There is a similar reduction in trips travelling between Sector 15 and Sector 19, where a $3 \%$ reduction also occurs. Similarly, there remains a significant number of trips travelling between both of these sectors, and this change has therefore been deemed acceptable.

### 4.11 Summary

The examination that was conducted on the matrix estimation process outputs shows that in terms of the $R^{2}$ analysis there is a high level of calibration across each model period.
Similarly, the trip length distribution plots show no significant change between pre and post matrix estimation matrices for the AM and PM peak, and a slight, acceptable change in the Inter Peak.

The sector to sector percentage and absolute change analysis shows that matrix estimation has not significantly adjusted the size and 'shape' of each prior matrix, with the AM and PM peak period matrices showing a good level of consistency pre and post estimation. The Inter Peak matrix shows slightly larger changes however this is deemed acceptable due to the lack of data available to alter the original 2009 prior matrices.

As a result, it was considered that the post matrix estimation matrices were appropriate and suitable for use in the updated model as the Base traffic matrices, particularly considering the areas where the proposed schemes are to be tested using this model are located. Care should be taken outwith this area, as the model calibration is primarily focused on Inverness area and the key routes approaching Inverness, including the A9, A82, A96, Millburn Road, Harbour Road, Culloden Road and Tower Road.

## 5. Assignment model development

### 5.1 Highway assignment

Highway demand is assigned to the network using the Assignment with ICA method, consistent with the 2014 model. Assignment with ICA is an extension of the Equilibrium Lohse method, including junction delay. In order to maintain consistency, all parameters are unchanged compared with the earlier model.

Generally, the Lohse Equilibrium (Assignment with ICA) procedure:

- provides a stable assignment;
- allows easier interpretation of the impact of network changes; and
- has a faster assignment time to the stochastic procedure.

### 5.2 Public transport assignment

The public transport is Headway based (without crowding), again, using parameters from the previous 2009 and 2014 models.

### 5.3 Generalised costs

The impedance parameters given in Table 5-1, Table 5-2 and Table 5-3 were updated during the development of the base model in line with WebTAG ${ }^{7}$.

Table 5-1: Impedance Parameters - AM Peak

|  | Car <br> Commute | Car In <br> Work | Car Non <br> Work | LGV | HGV |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Tcur Coefficient (a) | 3.434 | 5.121 | 2.37 | 3.536 | 3.674 |
| Distance Coefficient | 0.092 | 0.121 | 0.092 | 0.127 | 0.633 |

(b)

Table 5-2: Impedance Parameters - Inter Peak

| Distance Coefficient | 0.092 | 0.1220 | 0.092 | 0.127 | 0.636 |

(b)

### 5.4 Vehicle operating costs

Vehicle operating costs represent the additional costs of using a private vehicle, including fuel costs, depreciation and wear-and-tear. They are calculated for each link and are used to generate private vehicle costs for the demand (synthetic) model.

Vehicle operating costs have been previously calculated according to WebTAG ${ }^{8}$ guidance; they correctly omit non fuel costs for non-work purposes.

Table 5-4 : Vehicle Operating Costs

| Fuel costs 2018 | A | B | C | d |
| :--- | :--- | :--- | :--- | :--- |
| Average Car | 74.708 | 5.223 | -0.035 | 0.0004 |
| Non fuel costs 2018 | A1 | B1 |  |  |
| Average Car | 3.965 | 16.394 |  |  |
| Combined costs 2018 | A + B1 | A1 + B | C | D |
| Average Car | 91.102 | 9.188 | -0.035 | 0.0004 |

### 5.5 Model assignment / convergence parameters and statistics

The VISUM model assignment and convergence parameters adopted during the original base model development have been used for the highway assignment. The MFTM Development ${ }^{9}$ report states that the ICA assignment process was used, and has the requirements for two levels of convergence:

- Convergence of each highway assignment; and
- Convergence between highway assignments for the ICA calculations.

Though DMRB states that the value of duality gap should be less than $1 \%$, values of typically less than $0.1 \%$ are preferred, and would be necessary to develop information for the economic appraisal.

[^5]The level of convergence between highway assignments is determined using the following three criteria:

- The turn volumes from the last assignment are close to those from the previous assignment;
- The turn volumes of the last assignment match closely the last smoothed volumes (input to ICA); and
- The final delays of the assignment and those obtained from running ICA are close, i.e., ICA produces delays that are consistent with the assignment result."

The MFTM assignment is deemed to be converged when it meets five criteria. These are:

- GEH between link flows in the previous assignment and current assignment is less than 1 for $95 \%$ of all links;
- GEH between turning flows in the previous assignment and current assignment is less than 1 for $99 \%$ of all turns;
- GEH between turning flows in current assignment and smoothed ICA turning volumes is less than 1 for $99 \%$ of all turns;
- Relative gap between Blocking Back wait time and the Volume Delay Function wait time on links is less than 0.05 for $90 \%$ of all links; and
- Relative gap between Blocking Back wait time and Volume Delay Function wait time at turns is less than 0.05 for $99 \%$ of all turns.

AM, IP and PM peak models converged after 6, 5 and 16 iterations, respectively.
Convergence statistics for the last five iterations in each period are summarised in Appendix D.

## 6. Road model calibration

### 6.1 Introduction

The road model vehicle flows have been calibrated across a series of link counts as identified in Figure 4-1, Figure 4-2, and Figure 4-3. In accordance with WebTAG, calibration (and validation) flows are summarised for the peak hour within each model period.

### 6.2 GEH statistics

Calibration comparisons have been based on GEH statistics which is useful in comparing two different values of flow on a link. The GEH statistic is defined as:

The reason for introducing such a statistic is the inability of either the absolute difference or the relative difference to cope over a wide range of flows. For example, an absolute difference of $100 \mathrm{pcu} / \mathrm{h}$ may be considered a big difference if the flows are of the order of 100 pcu/h, but would be less important for flows of the order of several thousand pcu/h. Equally a $10 \%$ error in $100 \mathrm{pcu} / \mathrm{h}$ would not be important, whereas a $10 \%$ error in, say, $3000 \mathrm{pcu} / \mathrm{h}$ might mean the difference between building an extra lane or not.

### 6.3 WebTAG criteria

WebTAG criteria are strictly validation criteria, however, they have been used to assess the quality of both the model calibration and validation.

When comparing assigned and observed volumes, a GEH parameter of 5 or less would indicate an acceptable fit while links with GEH parameters greater than 10 require closer attention.

The difference statistic is also used; an assignment is assumed to be satisfactory where observed and modelled flows are within:

- $15 \%$ for flows between $700-2700 \mathrm{vph}$;
- 100vph for flows < 700 vph ; or
- 400vph for flows > 2,700vph.

### 6.4 Individual count sites

A summary of the number of individual count sites meeting guidelines is given in Table 7.1.

Table 6-1: Number of highway calibration screenline sites passing WebTAG criteria

| Peak | Difference <br> No. <br> Passes | Difference | GEH no <br> Passes |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | 88 | $90 \%$ | GEH <5 <br> $(\%)$ | GEH No. <br> passes <br> $<5$ | GEH <10 <br> $(\%)$ |  |
| AM Peak | 89 | $89 \%$ | 90 | $92 \%$ | 97 | $99 \%$ |
| Inter Peak | 89 | $89 \%$ | 92 | $91 \%$ | 100 | $100 \%$ |
| PM Peak | 89 | $92 \%$ | 100 | $100 \%$ |  |  |

Overall, the model shows a good level of calibration; approximately 92\% of the calibration sites meet the WebTAG $(G E H<5)$ while all sites have a $G E H<10$, with the exception of 1 in the AM Peak. A full list of sites is included as Appendix D.

## 7. Road Model Validation

Highway model vehicle flows have been validated across a series of screenlines, as follows:

- Screenline 1 - A96 west of Smithton Junction to Culloden Road;
- Screenline 2 - A82 to Telford Street;
- Screenline 3 - A82 Kenneth Street to Old Perth Road; and
- Screenline 4 - A82 Longman Road to Culcabock Road.

All screenlines have been defined specifically to inform the validation in and around Inverness (Figure 6.1). In accordance with WebTAG validation screenline flows are summarised for a peak hour within each model period.

The model has also been validated against observed journey times and highway assignment paths have also been reviewed to ensure routings are appropriate.

Figure 7-1 Location of the highway validation screenlines in Inverness

### 7.1 Highway Validation Screenlines

The WebTAG criteria for screenline validation states that the total screenline flow should be within $5 \%$ of the observed data in most cases. Previously, the guidance states that the screenline flows should have a GEH of less than 4, and whilst this has been removed from the guidance, it has been retained in the below analysis as it helps to show a goodness of fit.

Figure 7-1 to Table 7-4 show the screenline results for the AM Peak. In most instance the percentage change is higher than $5 \%$, however the flow crossing the screenline is relatively low in some instances, and the absolute difference also therefore relatively low. The GEH of 5 of the 8 screenlines are less the 4 , with 2 of the remining screenlines having a GEH of less than 4.5. The final screenline has a GEH of just above 5 .

Screenline 1 is above the recommended GEH of 4 in the westbound direction due to the traffic flow on the A96. As this is a strategic model, it does not have the level of detail to represent the dynamic nature of the build-up and dissipation of queues. As such the model may not be representing the behaviour of drivers as they approach the back of the queue at Raigmore Interchange, which would reduce the capacity of the A96 at this location. As a result, the level of traffic in the model travelling on this link, may be higher than observed as the model is not reflecting the slower moving traffic approaching Raigmore Interchange.
Overall, the screenlines in the AM peak generally correlates with the observed data in the AM Peak.

Table 7-1 Validation screenline 1 by count site: AM

| Screenline | Total | Obs | Mod | Diff | \% diff | GEH |

| Total | Westbound | $\mathbf{2 8 2 4}$ | $\mathbf{2 8 0 3}$ | $\mathbf{- 2 1}$ | $\mathbf{- 1 \%}$ | $\mathbf{0 . 3 9}$ |
| Total | Eastbound | $\mathbf{2 4 4 7}$ | $\mathbf{2 2 3 1}$ | $\mathbf{- 2 1 6}$ | $\mathbf{- 9 \%}$ | $\mathbf{4 . 4 7}$ |

Table 7-5 to Table 7-8 show the screenline results for the Inter Peak. In most instance the percentage change is higher than $5 \%$, however most are less than $10 \%$. As with the AM Peak, the flow crossing the screenlines are relatively low in most instances, and the absolute difference are therefore also relatively low. The GEH of 7 of the 8 screenlines are less the 4, which indicates a good level of correlation between the observed and modelled data. Therefore, it has been deemed that the Inter Peak validation is acceptable.

Table 7-9 to Table 7-12 show the screenline results for the PM Peak. In most instance the percentage change is $5 \%$ or lower, with 5 of the 8 screenlines meeting this criterion. Two of the three remaining screenlines have a change of $8 \%$, with a relatively small absolute change of less than 100 vehicles. This is reflected in the GEH analysis, where 7 of the 8 screenlines have a GEH of less than 4 , with the GEH of the remaining screenline being just over 4. As with the AM and Inter Peak periods, the PM peak therefore correlates well with the observed data.

### 7.2 Journey Times

Historical TomTom journey time data was acquired covering all of 2017 for 11 routes in Inverness to collect data on journey times and speeds. The routes are shown in Figure 8.2 and 8.3. The use of TomTom data is advantageous over moving observer surveys as the datasets typically have a larger sample size, meaning that the data is more robust.

WebTAG states that modelled journey times should be within $15 \%$ of observed, or 60 seconds if higher than $15 \%$ for $85 \%$ of routes. Generally, most routes show a very good relationship between the observed and modelled journey times, with $86 \%$ of routes being within $15 \%$ or 60 seconds of the observed for the AM Peak, $82 \%$ for the Inter Peak and $82 \%$ for the PM Peak.

Whilst the Inter Peak and PM Peak are slightly lower than the acceptable WebTAG criteria, the routes that are failing won't have a material impact on the schemes that the model is intended to test, with the exception of the A82 Longman Road Northbound. This route was broken down into five sections, A8082/A82 Roundabout to Kenneth Street/Tomnahurich Street Junction, Kenneth Street/Tomnahurich Street Junction to Telford Roundabout, Telford Roundabout to Shore Street Roundabout, Shore Street Roundabout to Harbour Road Roundabout and Harbour Road Roundabout to Longman Roundabout. This route fails to pass the WebTAG criteria in all three peaks, and consistently across the three peaks, the issue is the first section between the A8082/A82 Roundabout to Kenneth Street/Tomnahurich Street Junction. This section of the A82 is consistently fast as a result of the model failing to replicate the queuing that occurs from the traffic signals at the Kenneth Street/Tomnahurich Street junction. Removing this section of the route would result in a pass in all three peak periods. As the modelled journey time across the rest of the A82, and in particular the section from Shore Street Roundabout to Longman Roundabout, generally reflects the observed data, this has been deemed acceptable.

## 8. Demand model development

The demand model process has not been altered as part of this 2009 or 2014 model recalibration. The demand model development is discussed in Chapter 10 of the MFTM Development Report ${ }^{1}$. A brief summary of the process is in Figure 8-1.

Seeded base matrixinput to create reference case matrices

Base costs input for initial assignment. Initial assignmentschemed for to create new costs

Figure 8-1: MFTM demand procedure

## 9. Summary and Conclusions

Jacobs has been commissioned to prepare a Design Manual for Roads and Bridges (DMRB) Stage 2 Assessment of the A9/A82 Longman Junction Scheme and the DMB Stage 3 Assessment of the A9/96 Inshes to Smithton scheme.

In preparation for these assessments, it was agreed that the MFTM base be updated to reflect a base year of 2018 and include the West Link Phase 1 scheme.

This report summarises the revised calibration and validation of the Moray Firth Transport Model aimed at improving the network calibration within the study area of both scheme assessments, which is concentrated on Inverness and the immediate surrounding area.

Matrices have been developed from 2011 Census Travel to Work data, supplemented by observed origin destination data collected in 2009 from the original MFTM model development, and validated against RSI data collected in 2018. Matrix estimation has then been undertaken on each time period matrix to better fit observed highway volumes collected in February 2018.

The matrix changes at each stage of the development process have been reported. The sector to sector changes and trip length distribution highlights that the patterns of origins and destinations is similar in both pre and post estimation, and the areas where changes do occur tend to be where the traffic count information is located, which is the controlling factor in matrix estimation.

The model update process including network coding changes, the development of a new Car Commute matrix and the re-estimation of the road-based trip matrices have resulted in a link flow and GEH calibration criteria meet WebTAG criteria at over 89\%. The model validates satisfactorily against observed journey times, particularly in the vicinity of the A9/A82 Longman Junction and A9/A96 Inshes to Smithton Scheme.

Validation against remaining counts (not used in the calibration of the model) is also satisfactory, with the screenlines meeting the GEH of less than 4 in most cases, particularly in the Inter Peak and PM Peak models.

In summary, the calibration and validation statistics presented indicate that the base year VISUM model is consistent with WebTAG guidance for link count calibration and journey time validation. Matrix estimation changes between the initial and final versions are considered to be reasonable across all peaks, with the final matrix trip length distribution closely matching the prior values.

## Appendix A. Network changes

## Table A-1: Link type changes

| Link | From node | To node | Previous link type | New link type | Comment / change |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 19264313 | 114493377 | 114493378 | 11 | 12 | A82 changed to apply a different Speed Flow Curve |
| 19264469 | 114493463 | 114493479 | 45 | 55 | Harbour Road changed for Speed Flow Curve Purposes |
| 19264504 | 114493479 | 114493501 | 45 | 55 | Harbour Road changed for Speed Flow Curve Purposes |
| 19264517 | 114493472 | 114493509 | 11 | 12 | A82 changed to apply a different Speed Flow Curve |
