## Summary

In August 2001, the Scottish Executive appointed MVA to a term commission to maintain and further enhance CSTM3. This commission was named Transport Model for Scotland (TMfS). During this commission, TMfS was developed with a Base Year representative of 2002. During 2005 and 2006, TMfS was further enhanced, and as part of these enhancements, the model was calibrated and validated to a 2005 base year.

This report details the development, calibration and validation of the updated TMfS Highway Assignment Model (HAM) and the context within which it has been developed.

This report covers:

- the sources and processes used for updating the highway network, including link type changes, capacity and capacity index changes, modelled junction updates and the reporting of checking processes conducted;
- the sources and processes used for updating the assignment matrices, including zone boundary changes (for example, to allow for better representation of airport demand), creation of new prior matrices and new data used, discussion of the matrix estimation process and comparisons of matrices at stages in development;
- model calibration results, including strategic flow analysis, key link analysis and additional screenline analysis; and
- model validation results, including journey time analysis of 59 routes throughout the modelled area, screenline analysis of validation sites, freight flows and specific journey purpose flows as well as trip length distribution analysis.

The conclusions arising from this work are that the model is generally fit for purpose as a strategic highway model that can be used to assess major schemes and policy decisions as part of the TMfS modelling system. In addition, it is also fit for use as a source of travel demand and network structure for more localised models.

Each potential application of the model should be assessed in detail prior to ensure that the quality of the model is appropriate for the desired output as the quality of data input and consequently output differs across the entire modelled area.

## Abbreviations

Unless otherwise stated in the text, the abbreviations that may be used within this report are listed in the table below:

| CI | Capacity Index |
| :--- | :--- |
| CSTM3 | Central Scotland Transport Model 3 |
| CSTM3A | Central Scotland Transport Model 3A |
| CSTCS | Central Scotland Transport Corridor Studies |
| CVT | Cost versus Time |
| DALSAM | Dalkeith Sub Area Model |
| EATM | Edinburgh Area Transport Modal |
| GEH | Statistic for comparing modelled flows against observations |
| GIS | Graphical Information Services |
| HAM | Highway Assignment Model |
| KWAM | Kincardine Wide Area Model |
| LUTI | Land Use and Transport Interaction |
| OS | Ordinance Survey |
| PCUs | Passenger Car Units |
| RSI | Road Side Interview |
| SITM | Strathclyde Integrated Transport Model |
| STS | Scottish Transport Statistics |
| TMFS | Transport Model for Scotland |

### 1.1 Background

1.1.1 In 2001, MVA was commissioned by the Scottish Executive (now Transport Scotland) to undertake the Transport Model for Scotland (TMfS) project. The purpose was to build on existing transport models (eg CSTM3 and CSTM3A) and develop, support and maintain a methodologically enhanced and geographically expanded multi-modal forecasting tool.
1.1.2 The development of TMfS was completed in August 2004. The model has a Base Year of 2002. Since completion, the model has since been used for a range of infrastructure and policy assessments by MVA, other consultants, Local Authorities, the Scottish Executive and Transport Scotland.

## $1.2 \quad 2005$ rebase

1.2.1 In December 2005, MVA was instructed by Transport Scotland to undertake a rebase of TMfS to a 2005 Base Year. This work involved the update and enhancement of the model to incorporate newly available data and other procedural enhancements.
1.2.2 This report describes the rebase of the TMfS Highway Assignment Model to a 2005 Base Year. Separate reports detail the other aspects of the TMfS 2005 rebase such as the Public Transport Model and Demand Model:

- TMfS05 PTAM Cal Val Final Report, MVA May 2007; and
- TMfS05 Demand Model Development Report, MVA May 2007.
1.2.3 The rebased TMfS: 05 HAM was developed by drawing upon a variety of sources for network and junction information and by incorporating new traffic count data.
1.2.4 This report describes the development, calibration and validation of the 2005 TMfS Highway Assignment Model and the context within which it has been developed.
1.2.5 Figure 1.1 illustrates the geographical coverage of the TMfS modelled area.
1.2.6 Throughout this report, the original 2002 Base Year TMfS network will be referred to TMfS:02 and the new TMfS 2005 Rebase Model as TMfS: 05 .
1.2.7 This report assumes that the reader is familiar with the terminology and processes involved in transport model procedures of this nature. For further information, please refer to the TMfS Website, www.tmfs.org.uk.

### 1.3 Model Objectives

1.3.1 The key objectives of TMfS are to:

- provide robust traffic forecasts on all Trunk Roads within the model area over a twenty year horizon;
- enable traffic, economic and land-use assessments of proposed major inter-urban road schemes for corridor assessment and route option assessment;
- test the effects of the interaction between major inter-urban road and public transport schemes and major transport policy options such as;
- $\quad$ schemes to improve inter-urban public transport;
- $\quad$ schemes or policies aimed at reducing congestion in accordance with the Road Traffic Reduction Act, National Targets Act and Transport White Papers; and
- schemes which introduce road user charging (road tolls or congestion charging);
- provide consistent information and a framework for local scheme models as a basis for the development of Local Transport Strategies or with a view to testing potential strategies.

### 1.4 Structure of this report

1.4.1 Following this introductory Chapter, this Report includes the following Chapters:

- Chapter 2 describes the work undertaken on the network development. This covers the updating of all network and junction information and provides a description of the sources used;
- Chapter 3 describes the development of the base year assignment matrices and matrix estimation process used to create the TMFS:05 highway assignment matrices;
- Chapter 4 describes the development of the TMfS Final Highway Assignment Model and the incorporation of the 'Cost versus Time' Assignment method;
- Chapter 5 discusses the model calibration data through the presentation of screenline analysis on key strategic routes within the network;
- Chapter 6 discusses the model validation through the presentation of screenline and journey time analysis throughout the modelled network; and
- Chapter 7 provides conclusions and recommendations.

Figure 1.1 TMfS:05 Modelled Area

I ntroduction

## 2 Network Development

### 2.1 I ntroduction

2.1.1 This chapter considers the network developments that have been incorporated into the new 2005 rebased model.
2.1.2 Schemes incorporated in the 2005 Highway network are detailed below:

- A876 Kincardine Bridge Eastern Link;
- Glasgow Southern Orbital;
- M77 Extension (Fenwick to Malletsheugh);
- M876 Junction 2 Slip Road;
- A8011 Central Way, Cumbernauld;
- M8 Kingston Bridge;
- Network amendments near Gartcosh Park and Ride;
- Bargeddie Junction amendments;
- Ravenscraig Link Roads;
- M8 Junction 21 improvements;
- Cambuslang and Rutherglen Town Centre improvements;
- A71/A72 Garrion Bridge improvements;
- Central Edinburgh Traffic Management (CETM);
- Holyrood area network amendments;
- A1 Haddington to Dunbar dualling;
- Forth Road Bridge toll increases;
- Thornybank Road closure in Dalkeith; and
- A92 Dundee to Arbroath.
2.1.3 It should be noted that Finnieston Bridge, although due for completion in 2005, is not included in this rebase model as it was not completed at the time of the Highway network construction.
2.1.4 In addition to the network amendments mentioned above, 2005 Scottish Road Traffic Database (SRTDb) data have been used in model development. Some of these counts have been used in the calibration process where they have been utilised within the matrix estimation process 'MVESTM' while others have been used in the validation process. These processes are explained later within this report.
2.1.5 The remainder of this chapter is split into the following sections:
- link types;
- link capacities;
- speed/flow curve definition;
- link distance checks;
- link connectivity checks; and
- modelled junction data.

### 2.2 Link types

2.2.1 The link types used in the TMfS:05 are in line with those used in the Scottish Transport Statistics Note 24 (see Table 2.1), these remain consistent with TMfS:02. This Link Type numbering system has allowed analysis of model output to be easily compared with published statistics.

Table 2.1 Scottish Transport Statistics Link Type Definitions

| STS Link Type Number | Description |
| :--- | :--- |
| 1 | Trunk - Motorway |
| 2 | Trunk - Motorway slips |
| 3 | Trunk - A Roads Non- Built up |
| 4 | Trunk - A Roads Built up |
| 5 | Non Trunk - A Roads Non-Built up |
| 6 | Non Trunk - A Roads Built up |
| 7 | Minor Roads Non Built up |
| 8 | Minor Roads Built up |

2.2.2 In addition to those link types detailed in Table 2.1, two additional link types have been used in the network:

- $\quad 9$ - Banned HGV; and
- 10 - Bus Only.

### 2.3 Link capacities

2.3.1 The link capacities in TMfS: 05 remain consistent with those used in TMfS: 02.
2.3.2 Table 2.2 highlights the capacities (measured as PCUs per lane and not per carriageway) applied throughout the network. As part of the calibration process, these have also been manually amended in many areas. This process was undertaken to supplement the automated procedure and ensure that capacities provided a more appropriate reflection of conditions.

Table 2.2 Uniform Capacities by Link Type

|  | Link <br> Type 1 | Link <br> Type 2 | Link <br> Type 3 | Link <br> Type 4 | Link <br> Type 5 | Link <br> Type 6 | Link <br> Type 7 | Link <br> Type 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Capacity <br> per lane | 2400 | 1800 | 1800 | 1800 | 1600 | 1600 | 1000 | 800 |

### 2.4 Speed/ flow curve definition

2.4.1 Table 2.3 presents a descriptive list of TMfS speed/flow curves. These descriptions should not be taken literally but as an indication of the particular speed/flow curve specification. No changes have been made to the speed flow definitions for the updated TMfS: 05 from those used in TMfS: 02.

Table 2.3 Speed/ Flow Curve and Capacity I ndex Equivalence List

| TMFS CI | Description |
| :--- | :--- | :--- |
|  | City/ Urban Capacity I ndices |
| 2 | 40mph urban road (Tail) |
| 3 | 40mph urban road (No Tail) |
| 4 | 30mph urban road (Tail) |
| 5 | 30mph urban road (No Tail) |
| 6 | 30mph city centre road (Tail) |
| 7 | 70mph urban motorway |
| 8 | <70mph urban motorway |
| 9 | 30mph urban road junction approach |
| 10 | 30mph city centre road junction approach |
|  | Urban expressway |
| 11 | Suburban Capacity I ndices |
| 12 | 30mph suburban road (Tail) |
| 13 | 30mph suburban road (No Tail) |
| 14 | Major suburban road |
| 15 | 30mph suburban road junction approach |
|  | >30mph junction approach |
| 16 | Motorway, Dual, Rural Capacity I ndices |
| 17 | Rural routes |
| 18 | Wide single (10m) designed to TD9 |
| 19 | Ramp at grade separated junction |
| 20 | Rural motorway two lanes |
| 21 | Ramp junction approach |
| 22 | Rural motorway three or more lanes |
| 23 | Rural all purpose three or more lanes |
| 24 | Rural all purpose two lanes |
| 25 | Other Capacity I ndices |
|  | Traffic calming |
|  | 50mph expressway |

2.4.2 There are three types of curves used in the model (see Figure 2.1):

1. conventional - representing link and junction capacity constraints;
2. approach to a node that is not a junction or is not modelled as a junction; and
3. approach to a modelled junction.
2.4.3 Curve One (conventional) has an initial speed up to volume/capacity (V/C) limit and then drops linearly to the speed at capacity. Beyond capacity, it uses the so-called 'DOT 1A Tail' curve. Curve Two uses the same formula to capacity. Beyond capacity, speed is fixed at the capacity speed since on such links, only the link capacity/speed relationship operates, ie the downstream junction capacity is governed by a link with a Type One curve. Curve Three (modelled junction approach) is a fixed speed equal to the free-flow speed. On links approaching modelled junctions, all delay is calculated by the junction modelling
delay procedures. The exceptions are that the major arms at a priority junction or the circulating carriageway on large roundabouts are modelled as a series of priority junctions, which are based on time dependent queuing theory as used in ARCADY/PICADY/OSCADY.
2.4.4 This procedure ensures that intervening 'dummy nodes' (eg for presentation only) do not affect the overall link journey times.
2.4.5 The speed/flow curves used in the TMfS are shown in Table 2.4.

Table 2.4 TMfS speed/ flow curves

| Speed/ flow Curve | Capacity Index |
| :---: | :--- |
| Type1 | $1,3,5-7,10-11,13,16-19,21-25$ |
| Type2 | $2,4,12$ |
| Type3 | $8-9,14-15,20$ |

Figure 2.1 Speed Flow Curve Types

### 2.5 Link distance checks

2.5.1 The link distances for TMfS:05 are analysed in this section. Table 2.5 provides the results of the comparison between the Scottish Transport Statistics Note 24 (STS) and the TMfS:05 base network for Motorway and Trunk A Roads only. The
analysis shows there to be a comparable representation of the modelled distance for these strategic link types. The differences noted for Trunk A Roads are related to areas not covered by the model (eg the 'external north' area).

Table 2.5 TMfS:05 Motorway and Trunk A link distance analysis (kms)

| Road Type | STS (S) | TMfS (T) |
| :--- | ---: | ---: |
| Motorway | 383 | 390 |
| Trunk A | 2893 | 2797 |
| Grand Total | 3276 | 3187 |

### 2.6 Link connectivity checks

2.6.1 The network connectivity was checked and updated by:

- incorporating relevant details from sub-area models and their respective audits, such as DALSAM; and
- map based checks using 1:50,000 OS tiles, road maps and web resources.
2.6.2 Figures 2.2 and 2.3 show the detail of the TMfS: 05 highway network.

### 2.7 Modelled junction data

2.7.1 As stated in Section 2.1, the TMfS:05 Base Highway model was developed from TMfS:02 and, prior to that, the CSTM3A base network. Although extensive checks were made for the 2002 network, it was deemed necessary to re-check the approaches to modelled junctions.
2.7.2 This process was undertaken to avoid lengthy approaches to roundabouts, priority and signalised junctions. Any links with a distance in excess of 500 metres were manually checked and if necessary recoded to have a distance of 500 metres. This allowed vehicles approaching modelled junctions to maintain a greater speed for a longer distance than previously coded.
2.7.3 To complement the amendments made to the modelled junction approaches, the capacity indices, which designate the speed approaching the junction, were checked and where necessary amended.
2.7.4 Appendix A contains the extent of the areas within which modelled junctions are included in the model.

Figure 2.2 HAM Network Coverage

Figure 2.3 HAM Network (I nsert from Figure 2.2)

## 3 Matrix Development

### 3.1 I ntroduction

3.1.1 Matrix development for TMfS:05 involved enhancing the original TMfS:02 matrices through the following processes:

- conversion to the new TMfS:05 zone structure;
- zonal trip rate amendments;
- park and ride amendments; and
- matrix estimation.
3.1.2 The remainder of this chapter details the matrix development procedure introduced above: Section 3.2 describes the change in the zone system; Section 3.3 describes the matrix data used and Section 3.4 describes the development of the final matrices prior to matrix estimation while Section 3.5 describes the matrix estimation process used. All figures referred to are presented at the end of the chapter.
3.1.3 To present a comparison of the matrix totals during the stages of development a 14 sector system was developed (see Figure 3.1). This disaggregation of the modelled area facilitates the assessment of changes to the matrix in terms of travel patterns across the TMfS area.

### 3.2 Change in zone system

3.2.1 The TMfS:02 zoning system was developed based on amalgamations of 2001 Census Output Area Boundaries. The updated version of the model retained this zone structure, although those zones, which contained airports, were split. The purpose of this amendment was to allow for the separate modelling of airports.
3.2.2 The adoption of this new system means that, in forecast years, those zones, which represent airports, have their growth calculated directly from airport growth predictions and are excluded from the trip end and demand models.
3.2.3 Figures 3.2, 3.3 and 3.4 illustrate the new zones created in the areas around Edinburgh, Prestwick and Aberdeen airports respectively. No new zones were required for Glasgow airport as it already had its own zone. Figure 3.5 shows the final network wide zoning system. To see the model zoning system in more detail, see www.tmfs.org.uk

### 3.3 Matrix Data

3.3.1 The matrices for TMfS: 05 were built using forecast matrices from TMfS:02. 2005 output planning data from the TELMoS model was also used to adjust trip rates in those parts of the matrix, which were deemed to have an unusually high or low level of trip making.
3.3.2 No new RSI data was collected or used within the TMfS: 05. The RSI sites used in the original TMfS are described in detail in the TMfS:02 Calibration and Validation Report.

### 3.4 Prior development

3.4.1 The prior matrix for TMfS was developed in three principal stages, as illustrated in Figure 3.6.
3.4.2 TMfS: 02 forecast matrices were used as the starting point for the creation of the new TMFS:05 matrices. The TMfS:02 prior matrices, which underlie these matrices, were built from CSTM3 matrices, CSTCS RSI matrices, Glasgow SATURN matrices, ASAM matrices and A80 Traffic Model Highway Matrices.
3.4.3 These TMfS: 02 forecast matrices were then converted into the new TMfS:05 zoning system as described in section 3.2. This was, achieved by splitting the airport zones. The part containing the airport retained the same pattern as the old zone as it was the dominant trip generator of the zone. The remainder of the zone was, given a similar travel pattern to that of a nearby zone with comparable trip generating attributes.
3.4.4 Having done this, amendments were, made to the assignment matrices based on the most up to date 2005 planning data available at the time of calibration. This data was, used to amend those zonal trip rates, which were deemed abnormally low or high. The process used to do this was as follows:

- using planning data and trip matrix productions and attractions, production and attraction rates for each zone were, calculated along with model wide rates;
- $95 \%$ confidence intervals were then calculated for both production and attraction rates. Zones whose rates fell outside these values were, amended by applying the upper or lower 95th percentile rate to these zones; and
- finally, the revised productions and attractions were, factored to ensure a match with the original productions and attractions. These revised production/attraction trip ends were then 'furnessed', using the original matrix to obtain the pattern.
3.4.5 The base network was then assigned with these matrices in order to attain network costs. These matrices and costs were, then run through the Park and Ride process to produce post Park and Ride Prior demand matrices. This was, undertaken to achieve a better trip pattern, than the absolute origin and destination used before. These matrices were, then used in the matrix estimation process. The reader should note that the Park and Ride procedure is linked between time periods, and that all trips will have a corresponding reverse trip.

### 3.4.6 Those Park and Ride sites included are shown in Table 3.1 below.

| P\&R Site | Type | P\&R Site | Type | P\&R Site | Type |
| :---: | :---: | :---: | :---: | :---: | :---: |

Figure 3.1 Park and Ride sites included in the Base Model

### 3.5 Matrix Estimation

3.5.1 The calibration of the assignment process was undertaken using the CUBE based Matrix Estimation program MVESTM.
3.5.2 MVESTM uses a wide variety of data sources, each of which has a confidence level assigned to it. Through this approach, it is possible to manipulate MVESTM to make changes in the areas where the expressed level of confidence is lower. This feature was used to estimate the 2005 HAM matrices and used the following data:

- prior matrix (with a confidence of 60 );
- $\quad$ trip end data ( with a confidence of 80 );
- paths; and
- traffic counts (with a confidence of 100 for those updated with 2005 SRTDb data, old counts from 2002 were given a confidence of 55).

## Prior Matrix

3.5.3 All OD pairs were given the same confidence. The pattern from the RSI sites is contained within the forecast matrix from TMFS:02, which was used as the starting point for the prior matrices. As there was already a high level of confidence in this pattern, it was decided that all movements should be given the same level of confidence.

## Trip Ends

3.5.4 The trip ends were given a higher confidence level than that of the matrix. The confidence level expressed in the trip ends was higher as these had been amended by the planning data adjustments.

## Paths

3.5.5 MVESTM also requires a set traveller paths from the model. The trip points used in the estimation process were representative of the best paths available after a run of the model with a new matrix. MVESTM and the traffic model were run iteratively with successively improving paths and costs being fed into the MVESTM program. 'Burrell paths' were built after each modelled time period achieved convergence following capacity restraint assignment. MVESTM was provided with three sets of paths built separately for each time period after the last iteration of assignment. It was considered that these were most appropriate as they were shown to represent stable network conditions.

## Traffic Counts

3.5.6 The count data used for the estimation process was that collected for the RSIs used in matrix development. In addition, a selection of 2005 SRTDb count sites were also included. From these count locations, count screenlines were created for use in MVESTM. Appendix B contains graphical representations of the locations of the screenlines used in calibration. Traffic counts were given a high confidence if they had been collected since the previous calibration of the model and a lower confidence if the count had been used in the previous calibration of TMfS.

### 3.6 Matrix Development Comparisons

3.6.1 Tables 3.2 to 3.13 detail the peak hour matrix totals for the Pre-Planning Data Amendments, Pre-Park and Ride Prior, Post Park and Ride Prior (Prior meaning
before MVESTM) and Final Highway matrix totals. For all analysis, the matrix values are in PCUs $\times 10$.
3.6.2 From the tables it can be seen that the alterations due to the planning data do not change the matrices significantly at a 14 sector level. However, zones with anomalous trip rates have been removed.
3.6.3 It can be seen from these matrices that a small number of short distance trips have been added due to the Park and Ride, particularly Fife to Edinburgh in the AM and Edinburgh to Fife in the PM. This is as a result of large Park and Ride sites, like Ferrytoll, attracting trips to Park and Ride. Longer distance movements see a small decrease in the number of trips.
3.6.4 The MVESTM procedure, has also added a small number of short distance trips. There are a number of movements which have experienced
3.6.5 Dundee to Perth movements have experienced increases in the matrix estimation process. The reason this has occurred is that the new SRTDb counts from 2005 for the A90 between Perth and Dundee are around $50 \%$ higher than those used in TMfS:02. The Prior MVESTM matrix is an amended TMfS: 02 forecast matrix, which did not generate this level of growth on this link. Due to this increased count, which, as a result of being from 2005, has a high confidence, the matrix estimation process has added in additional trips making this movement.
3.6.6 Glasgow and Strathclyde to Edinburgh movements have experienced decreases during the matrix estimation phase. This is due to a similar reason to that stated in 3.6.5. However, the change in this case is not as significant. In this case, the new SRTDb counts are lower than the forecast growth in traffic (particularly along the M8). Because of these new counts, the matrix estimation process reduced the number of trips in this corridor.
3.6.7 A similar situation exists in the Scottish Borders, particularly in the Galashiels area, where the new SRTDb counts that were used, were significantly higher than the forecast TMfS: 02 counts. This resulted in an increase in trips in this area during the matrix estimation process. However, it should, be noted that in this geographical area, many intra-zonal trips are missing from the matrix through an absence of observed travel pattern data and larger zones.
3.6.8 Some of the PM sector-to-sector matrix totals also change significantly during the matrix estimation process. A PM forecast matrix is largely based upon a transpose of the AM Peak matrix. The issues discussed in 3.6 .5 to 3.6 .7 can be seen in the PM matrix, but in reverse.
3.6.9 Overall, the change in the matrix from the prior matrices to the final post-MVESTM matrices in absolute terms is very small.

## 4 Assignment Model Development

### 4.1 I ntroduction

4.1.1 The assignment procedure adopted for TMfS: 05 HAM is the same as that used in TMfS: 02, namely a 'Volume Averaged Capacity Restraint Assignment' based on 'All or Nothing' paths at each iteration (for four user classes).
4.1.2 The TMfS: 05 HAM includes:

- four separate user classes are assigned to the network. These are; Car In Work, Car Non Work, LGV and OGV; and
- the assignment adopts the principles of the 'Davis Method', which allows for modelling of tolls to be undertaken during the main assignment rather than as a separated modelling process.
4.1.3 This chapter will discuss the assignment procedure used for TMfS: 05 HAM plus the incorporation of the 'Cost versus Time’ Assignment Method.

### 4.2 Assignment procedure

4.2.1 The assignment procedure adopted is a 'Volume Averaged Capacity Restraint Assignment' based on 'All or Nothing' paths at each iteration. This procedure has the following benefits:

- model convergence can be checked;
- the assignment can continue for as many iterations as required to achieve a user pre-defined level of convergence;
- cars, goods and light vehicles are assigned using the same path building technique on every iteration; and
- 'All or Nothing' path building at each iteration gives a comprehensive multi-routing assignment.
4.2.2 The assignment procedure carries out a 'Volume Averaged Capacity Restraint' throughout the whole modelled area, based on 'All or Nothing' paths for ' $n$ ' iterations until the model is fully converged. The principal features of this assignment process are as follows:
- the model operates over three one hour time periods;
- 'All or Nothing' path building is carried out separately for the four user classes (car in work, car non work, LGV and OGV) using the CUBE program AVROAD; and
- 'Volume Averaged Capacity Restraint' (within the CUBE program AVCAP) ensures that each iteration of restraint is based on the average of all previous iterations (during capacity restraint calculations, all user classes are combined into total PCUs).
4.2.3 'Volume Averaged Capacity Restraint' is ideally suited to congested urban networks, where the level of traffic leads to different 'All or Nothing' paths on successive iterations, and so to multi-routing through the 'Volume Averaging' procedure. However, an uncongested rural area will tend to give mono-routing results because of the low level of traffic compared with capacity and the reduced routing choices. As a result, the optimum paths on the first iteration will remain the optimum throughout the assignment.

### 4.3 Cost versus Time Assignment Method

4.3.1 The 'Cost versus Time Assignment Method' (CvT Method) was incorporated within the TMfS:02 assignment procedure as it allows tolling tests to be undertaken without the requirement of a separate model, as was the case in both CSTM models ( 3 and 3A). This is still the case within TMfS: 05 .
4.3.2 The method is described in the paper entitled "Cost versus Time Equilibrium over a Network" by Fabien Leurent in the "European Journal of Operational Research". The paper describes the theory and demonstrates that the method converges to equilibrium.
4.3.3 Rather than increase the number of user classes, this method varies the willingness to pay weighting applied to tolls in the route choice generalised cost from iteration to iteration. The willingness to pay weighting is in fact randomly sampled from a distribution, which is representative of the total population. The mechanics of the process are very similar to the stochastic user equilibrium process.
4.3.4 The generalised cost for route choice is defined for a link in the network as:
$\mathrm{C}=\mathrm{a} *$ time $+\mathrm{b} *$ distance $+\mathrm{c} *$ toll
4.3.5 In the equation above, ' $a$ ' is a time parameter, ' $b$ ' a distance parameter and ' $c$ ' $a$ cost parameter.
4.3.6 Where ' $c$ ' is the link generalised cost and ' $a$ ', ' $b$ ' and ' $c$ ' are parameters. In the CSTM, tolling model there was one value of ' $c$ ' for each user class (for a particular year) and these values are fixed for the whole assignment. In the CvT method, there are no additional user classes compared with the standard (ie non-toll) model but the parameter ' $c$ ' (one for each user class) is varied by random sampling at each iteration of the highway assignment procedure.
4.3.7 The distributions from which the 'willingness to pay' for each user class are randomly sampled remain the same between TMfS:02 and TMfS:05.

### 4.4 Model Convergence

4.4.1 The previous methodology for calculating model convergence as used in CSTM3 did not require the inclusion of the tolling element of the generalised cost as this did not vary by iteration. As mentioned above, the CVT method varies the generalised cost co-efficient attached to tolls randomly from iteration to iteration. This required a change to the existing methodology to add the tolling cost to the network cost (ie time and distance) by iteration.
4.4.2 From the iteration number and the total cost, a normalised regression statistic is calculated using the following formula (which provides the gradient of the line of the graph of iteration number ' X ' versus total cost).

$$
a=\frac{n \sum x y-\sum x \sum y}{n \sum(x)^{2}-\left(\sum x\right)^{2}} / c
$$

where:

- a is the gradient;
- x is the iteration number;
- y is the total cost;
- c is the total cost on the current iteration; and
- n is the number of iterations over which the regression is calculated.
4.4.3 The regression statistic is normalised using the total cost of the current iteration, to leave it unitless as a pure parameter.
4.4.4 The HAM acceptance criteria is that the level of convergence must be less than or equal to the DMRB recommended value of $1 \%$ on three successive iterations for the assignment procedure to automatically terminate. This is a very exacting level of convergence for this size of model and is necessary to ensure that reliable data is passed to other elements of the modelling process, most importantly, the economic analysis element.
4.4.5 The number of iterations required to reach convergence within the base model were:
- AM Peak - 77 iterations;
- Inter-Peak - 36 iterations; and
- PM Peak - 68 iterations.

## 5 Calibration

### 5.1 I ntroduction

5.1.1 In this chapter, the model is examined in detail to demonstrate its level of calibration. Journey time validation and validation against independent counts are presented in the following chapter. All observed and modelled values are in PCUs.
5.1.2 The screenline locations and traffic count data used for calibration purposes are those used in the MVESTM process. In total, 649 sites have been used in the MVESTM procedure. Of these 649 sites, 92 formed part of multi-point screenlines and, as such, are duplicates. The number of unique screenlines is 557 .
5.1.3 The analysis of the modelled screenline and link flows makes use of a summary statistic known as GEH, which is defined as:

GEH $=\left((\text { observed }- \text { modelled })^{2} /\left(0.5^{*}(\text { observed }+ \text { modelled })\right)^{0.5}\right.$
5.1.4 The GEH value is designed to be more tolerant of large percentage differences at lower flows. For example, one would not normally be concerned about a modelled flow that differed from a count by $40 \%$ if the count was only 100, but one would if the count were 1000. The reason for introducing such a statistic is the inability of either the absolute difference or the relative difference between the modelled flow and count to reflect differences over a wide range of flows such as are present in the HAM.
5.1.5 For a model such as the HAM, given its size, complexity, and the magnitude of traffic flows, we would normally expect screenline GEH values to meet the following targets to achieve a high standard of calibration:

| - | $\mathrm{GEH}<5$ | $60 \%$ of all sites; |
| :--- | :--- | :--- |
| - | $\mathrm{GEH}<7$ | $80 \%$ of all sites; |
| - | $\mathrm{GEH}<10$ | $95 \%$ of all sites; and |
| - | $\mathrm{GEH}<12$ | $100 \%$ of all sites. |

### 5.2 Key Strategic Screenline Flows

5.2.1 Key strategic screenlines are defined for the purposes of model calibration, as shown in Appendix B. One strategic screenline covers traffic flows across the Forth Estuary on the Kincardine Bridge, the Forth Road Bridge and at Stirling (calibration screenlines 17 and 117). The results for TMfS:05 are presented in Table 5.1 and the results for TMfS:02 are detailed in Table 5.2 for purposes of comparison.

Table 5.1 TMfS:05 Forth Estuary Strategic Screenline

| Direction | Time <br> Period | Observed | Modelled | Dif | \% Dif | GEH |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: |
| Northbound | AM | 4696 | 4652 | -44 | -0.9 | 0.6 |
|  | IP | 3446 | 3456 | 10 | 0.3 | 0.2 |
|  | PM | 6096 | 5694 | -402 | -6.6 | 5.2 |
| Southbound | AM | 5072 | 5179 | 107 | 2.1 | 1.5 |
|  | IP | 3312 | 3606 | 294 | 8.9 | 5.0 |
|  | PM | 4387 | 4530 | 143 | 3.3 | 2.1 |

Table 5.2 TMfS:02 Forth Estuary Strategic Screenline

| Direction | Time <br> Period | Observed | Modelled | Dif | \% Dif | GEH |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: |
| Northbound | AM | 4467 | 4321 | 146 | 3.3 | 2.2 |
|  | IP | 3352 | 3239 | 113 | 3.4 | 2.0 |
|  | PM | 5664 | 5447 | 217 | 3.8 | 2.9 |
| Southbound | AM | 5271 | 5281 | -10 | -0.2 | 0.1 |
|  | IP | 3537 | 365 | -68 | -1.9 | 1.1 |
|  | PM | 4790 | 4530 | 260 | 5.4 | 3.8 |

5.2.2 TMfS: 05 Northbound screenlines show that observed and modelled flows differ by between a GEH of 0.2 and 5.2 and the Southbound screenline differs by between a GEH of 1.5 and 5.0. Comparing TMfS:05 GEH's with those of TMfS:02 GEH's, the Northbound AM and Inter-Peak demonstrate an improvement along with the Southbound PM peak. Although the opposite directions and time periods show changes in GEH values, these are deemed minimal with the high level of calibration demonstrated.
5.2.3 The strategic screenline across the River Clyde includes all crossings from the Albert Bridge, east of Glasgow City Centre, to the Erskine Bridge in the west (calibration screenlines 246 and 346). Table 5.3 presents TMfS:05 observed versus modelled flows for this screenline while Table 5.4 presents TMfS:02 screenline data.

Table 5.3 TMFS:05 Clyde Strategic Screenline

| Direction | Time <br> Period | Observed | Modelled | Dif | \% Dif | GEH |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: |
| Northbound | AM | 15426 | 15137 | -289 | -1.9 | 2.3 |
|  | IP | 9807 | 10130 | 323 | 3.3 | 3.2 |
|  | PM | 11208 | 11433 | 225 | 2.0 | 2.1 |
| Southbound | AM | 12386 | 13816 | 1430 | 11.6 | 12.5 |
|  | IP | 10183 | 10679 | -496 | -4.8 | 4.9 |
|  | PM | 15848 | 16480 | -632 | -4.0 | 5.0 |

Table 5.4 TMfS:02 Clyde Strategic Screenline

| Direction | Time <br> Period | Observed | Modelled | Dif | \% Dif | GEH |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: |
| Northbound | AM | 13973 | 14604 | 631 | 4.5 | 5.3 |
|  | IP | 9835 | 9867 | 32 | 0.3 | 0.3 |
|  | PM | 11823 | 11573 | -250 | -2.1 | 2.3 |
| Southbound | AM | 12262 | 12335 | 73 | 0.6 | 0.7 |
|  | IP | 9562 | 9474 | -88 | -0.9 | 0.9 |
|  | PM | 15277 | 14326 | -951 | 6.2 | 7.8 |

5.2.4 TMfS: 05 Northbound screenlines show that observed and modelled flows differ by between a GEH of 2.1 and 3.2 and the Southbound screenline differs by between a GEH of 5.0 and 12.5. TMfS: 05 results improve as a result of the Northbound AM and PM Peak in the rebased network. Other GEH values worsen, in particular the Southbound AM Peak. The modelled flow has increased by 1,500 vehicles from TMfS: 02 while the observed count only increases by 100 vehicles. The difference in flow in this instance has led to a large GEH value. The principal reason for this increase is during calibration, modelled flows will increase to complement adjacent counts, which may be either new or updated from that in TMfS: 02.
5.2.5 The high GEH southbound in the AM Peak is partly due to the mixture of old and new count data used. In this instance, the new count is lower than the forecast growth in flow. Part of the reason for this is due to the unavailability of 2005 count data in certain locations and therefore, 2002 data has been used which may underestimate the actual conditions. MVESTM could not remove enough of the forecast trips from this screenline to match these lower counts. This mixture of old and new data also leads to wide variability of GEH scores on individual links across the Clyde estuary.
5.2.6 Table 5.5 presents TMfS:05 results for Strategic Screenline Three, which covers traffic flows across the Tay Bridge (calibration screenlines 27 and 127). Table 5.6 presents the results for TMfS:02 for comparison.

Table 5.5 TMfS:05 Tay Strategic Screenline

Table 5.6 TMfS:02 Tay Strategic Screenline

| Direction | Time <br> Period | Observed | Modelled | Dif | \% Dif | GEH |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: |
| Northbound | AM | 1957 | 1813 | -144 | -7.4 | 3.3 |
|  | IP | 725 | 665 | -60 | -8.3 | 2.3 |
| Southbound | PM | 909 | 855 | -54 | -5.9 | 1.8 |
|  | IM | 718 | 670 | -48 | -6.7 | 1.8 |
|  | PM | 722 | 633 | -89 | -12.3 | 3.4 |
|  | 1442 | 1312 | -130 | -9.0 | 3.5 |  |

5.2.7 TMfS: 05 Northbound screenlines show that observed and modelled flows differ by between a GEH of 0.7 and 3.8 and the Southbound screenlines differ between a GEH of 0.2 and 4.3. The GEH values of the screenlines display minimal changes between TMfS:02 and TMfS:05. As can be seen from the observed values for the Tay strategic screenline, no new count data has been used in the calibration process.

### 5.3 Other screenline flows

5.3.1 As discussed in paragraph 5.1.2, the calibration screenlines presented in this chapter are the same as those used in the MVESTM process (Appendix B).
5.3.2 Given that the principal aim of this project is to predict strategic road flows throughout the modelled area, the calibration sites can be conveniently divided into two groups:

- key links (single points on major roads); and
- multi-point screenlines.

## Key Links

5.3.3 Traffic count data was available for most key trunk and principal roads within the modelled area. The majority of new TMfS:05 count data was obtained from SRTDb. The links presented here may also exist as part of multi-point screenlines but are presented separately, given the importance of these routes to the objectives of the model. Appendix C presents tables for the AM peak, Inter-Peak and PM peak observed/modelled total flows for the 253 Key Links, which have been used to achieve calibration throughout the HAM. Previously in TMfS: 02, 137 Key Links were reported. The GEH statistic (described in paragraph 5.1.4) has been used to assess the overall acceptability of these results. For ease of comparison between the TMfS:02 and the TMfS: 05 results, the TMfS: 02 results are contained in brackets in all tables.
5.3.4 These Key Links cover the major roads of the modelled area. Table 5.7 details the GEH analysis.

Table 5.7 Key Links Flow GEH Analysis

|  | $\%$ of sites with GEH value (TMfS:02 values in brackets) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ | $\leq 10$ | $\leq 12$ | $\leq 15$ |
| AM | $62(60)$ | $78(75)$ | $89(90)$ | $95(95)$ | $100(99)$ |
| IP | $79(75)$ | $90(89)$ | $96(96)$ | $99(99)$ | $100(100)$ |
| PM | $66(62)$ | $79(78)$ | $91(92)$ | $95(97)$ | $99(99)$ |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |

5.3.5 The vast majority of the GEH values are better than the target of 12 , indicating that the major routes of the modelled area are sufficiently well calibrated. The GEH percentages compare favourably against those of TMfS:02 results. In addition, TMfS:05 is calibrated to a significantly larger database of traffic counts than TMfS:02. In this instance, the number of sites that have GEH values of $\leq 5$ and $\leq 7$ for all time periods are greater than TMfS: 02 values.
5.3.6 The highest GEH statistics are 16.7 in the AM Peak; 14.7 in the Inter-Peak; and 18.3 in the PM Peak. For all those Key Links with a GEH value greater than 15 (1, 0 and 2 in the AM, Inter-Peak and PM peaks respectively), only one has less trips assigned than their traffic count. On investigation, the difficulties lie in the relative coarseness and large size of zones in the vicinity and the corresponding lack of assigned intrazonal trips, which would influence traffic flow on these links.

## Multi-Point Screenlines

5.3.7 In addition to single link calibration points, a number of screenlines with multiple observations were prepared. These multi-point screenlines were used to calibrate the model across a cordon or along a wide screenline. Appendix D provides a detailed analysis of these multi-point screenline flows.
5.3.8 Table 5.8 summarises the screenline GEH analysis for each time period for all 41 multi-point screenlines used in the calibration of the model. Previously, 48 two-
way multi-point screenlines were used in TMfS: 02 . In general, the screenline GEH value is better than the target of 12 . Table 5.8 shows that the majority of GEH values lay within or close to their target levels.

Table 5.8: Multi Point Screenlines GEH Analysis

|  | \% of sites with GEH value (TMfS:02 values in brackets) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ | $\leq 10$ | $\leq 12$ | $\leq 15$ |
| AM | $62(57)$ | $77(81)$ | $91(94)$ | $97(95)$ | $100(100)$ |
| IP | $67(78)$ | $81(88)$ | $94(95)$ | $99(98)$ | $100(100)$ |
| PM | $62(71)$ | $75(79)$ | $90(92)$ | $96(96)$ | $99(99)$ |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |

5.3.9 Although the multi-point percentages are lower in some time periods than TMFS:02, it is noted that there was a significant increase in the total number of screenlines reported on and consequently a wider geographic area was covered. With this in mind, the majority of targets are met, confirming a good level of calibration.
5.3.10 Appendix E provides a detailed breakdown of the flows on each individual link used in calibrating the HAM for all three time periods. Table 5.9 summarises the GEH analysis of these 230 sites. Appendix E also shows these GEH values as coloured links on the network for each modelled time period.

Table 5.9 Link Flows-Calibration Screenlines

|  | \% of sites with GEH value (TMFS:02 values in brackets) |  |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ |  |  |  |  |  | $\leq 10$ | $\leq 12$ | $\leq 15$ |
| AM | $60(60)$ | $74(76)$ | $88(90)$ | $94(95)$ | $99(99)$ |  |  |  |  |  |
| IP | $72(72)$ | $84(85)$ | $95(94)$ | $99(97)$ | $100(99)$ |  |  |  |  |  |
| PM | $62(60)$ | $76(75)$ | $89(89)$ | $93(94)$ | $98(98)$ |  |  |  |  |  |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |  |  |  |  |  |

5.3.11 A large number of the links in the TMfS: 05 network are within the GEH target of 12 , and the vast majority are better than the target of 15 . However, the highest GEH values are 23.2 in the AM peak, 16.0 in the Inter-Peak and 19.7 in the PM peak respectively. These sites were investigated and the difficulties lie in the relative coarseness and large size of zones in the vicinity and corresponding lack of assigned intra-zonal trips, which would increase traffic on these links. In total there are 649 screenlines used in the calibration process. Of these 649 screenlines, 92 formed part of multi-point screenlines, and as such, are duplicates. The actual number of unique screenlines is 557 , which compares to 475 used in the calibration of TMfS:02. Of all the Key Links with a GEH value greater than 15, 8 are in the AM peak, 1 in the Inter-Peak and 14 in the PM peak.
5.3.12 The TMfS: 05 values are similar to those of the TMfS: 02 values, with changes being relatively marginal.
5.3.13 Appendix F contains graphical illustrations of the screenline results for the three time periods.

### 6.1 I ntroduction

6.1.1 Validation is the process of checking how well the model compares with data independent of the calibration process and will be presented using the following information:

- journey time data;
- count data not used in calibration; and
- $\quad$ trip length distribution analysis.
6.1.2 In addition, screenline analysis has been undertaken on HGVs. This analysis was not used during calibration as the calibration process considered flows in terms of total PCUs only.

### 6.2 J ourney times

6.2.1 As part of the validation process, observed and modelled journey times have been compared across 59 routes throughout the modelled area, this includes two additional TMfS: 05 journey times on the M8. Table 6.1 and Figure 6.1 (at the end of this chapter) detail the 'Edinburgh Area Urban Journey Routes'. Each individual route is illustrated in Appendix G. Table 6.1 also shows the mean observed and modelled journey times for each route in each time period.

6.2.5 The ' $A$ ', ' $B$ ', and ' $D$ ' routes were surveyed at least six times in each direction in each modelled time period; the 'C' routes were surveyed at least four times. Two new routes, annotated as ' $E$ ' (in the tables above), have been added to the validation analysis procedure, since TMfS: 02, and have been surveyed six times (in each direction). The resulting journey times were analysed to determine the mean journey time and standard error. This in turn led to a range of acceptable journey times given a 95\% confidence interval that would be expected for each route, given that the journey times would vary in the form of a normal distribution.
6.2.6 The confidence intervals used were calculated using the following formula:

95\% Confidence Interval for Population = Sample Mean $+\mathrm{t}(0.025, \mathrm{n}-1) * \mathrm{~s}$
where:
n - sample size;
t - two tailed t -test with $5 \%$ level of significance and $\mathrm{n}-1$ degrees of freedom; and
s - standard deviation of sample.
6.2.7 Appendix H contains detailed journey time analysis for each route detailed in Tables 6.1 to 6.4. These results are, shown graphically along with the confidence intervals and are discussed further in this chapter.
6.2.8 It should be taken into consideration that the journey time routes used in the validation process, except for route ' E ', are from TMfS:02 and have not been factored to a 2005 base level. In addition, some of the journey time routes have been physically altered as a result of newly constructed Highway schemes, an example being Route B10 between the A713 Whitletts Road / B749 Craigie Road and A77 / B764. The M77 Extension between Fenwick and Malletsheugh has been completed and included in the network. This will therefore have an effect on the network flows and the journey time. A complete list of highway schemes that have been coded in the TMfS: 05 network are located earlier in Chapter 2 of this report.
6.2.9 For the Edinburgh area journey times, there are eight instances where a journey time lies outwith its $95 \%$ confidence intervals (see Appendix H). Route B8_2 consistently lies outwith its respective confidence intervals over all three time periods. These routes are listed in Table 6.5 below:

Table 6.5 Edinburgh Urban Area J ourney Routes

| Time <br> Period | Route ID | Description | Additional <br> Periods |
| :--- | :--- | :--- | :--- |
| AM | B8_2 | A6095 Dumbbell Roundabout A1 Slips to M9 J3 <br> On Slip / A803 |  |
|  | B13_1 | A720 / A701 Burdiehouse Road to A1 West Slips |  |
| IP Newcraighall Roundabout |  |  |  |

6.2.10 The AM period has two journey time routes that lie outside their confidence intervals. The modelled journey time for Route B8_2 is faster than the observed time whereas, Route B13_1's modelled time is marginally longer.
6.2.11 The Inter-Peak contains three such routes; these are dealt with in turn. The model journey time for Route 1_2 is around 10 minutes quicker than the observed time. However, it must be noted that the Central Edinburgh Traffic Management scheme has been included in TMFS:05, it is anticipated that some routes that pass through the centre of Edinburgh would differ from their recorded journey time. Route B8_2, lies outwith its confidence interval, however, it must be noted that the confidence intervals for achieving validation of this journey are very small. Route 13_2 journey time is marginally slower that the observed time.
6.2.12 The PM Peak period contains three routes whish lie outwith their confidence intervals. Route B2_1's modelled journey time is around seven minutes faster than. The worst offender in this time period is Route B8_2, which is around 10 faster than the observed data.
6.2.13 In general, the Edinburgh Area Journey Times demonstrate a high level of validation.
6.2.14 For the Glasgow Area Journey Times there are 14 instances where a modelled journey time lies outwith with its $95 \%$ confidence intervals in the AM Peak period, 21 in the Inter-Peak and 19 in the PM Peak Period. These routes are listed in Table 6.6 below:

Table 6.6 Glasgow Area Urban J ourney Times

| Time | Route ID | Description | Additional Time Periods |
| :--- | :--- | :--- | :--- |
| Period |  | Motherwell - Carmyle |  |
| AM | C2_2 | A73 Newhouse - A726 Nitshill |  |
|  | C7_2 | A77 - East Kilbride |  |
|  | C14_1 | George Square / Castle St (Anti- | IP |
|  | C29_1 | Mockwise) |  |

|  | C33_1 | A80 M9 J9 Stirling to J Provan |  |
|  | D2_1 | Glasgow Zoo to A775 Newhouse | IP/PM |
|  | D3_1 | A725 Raith to A89 Coatbridge |  |
|  | A8_2 Edinburgh Road to Alexander |  |  |
|  | D6_1 | Park St |  |
|  | A89 Baillieston Lights to Millerston | IP/PM |  |
|  | D7_1 | Street | A74 Glasgow Zoo to A74 Fielden |

## AM Peak Period

6.2.15 Routes C2_2 and C33_1 both lie outwith their confidence interval, however, it must be noted that the confidence intervals for achieving validation of this journey time are only a minute either side of the average, and for a strategic model such as TMFS: 05 is very difficult to match this journey time.
6.2.16 Routes D2_1, D3_1, D5_2, D6_1, D7_1, D8_1, D9_1, D9_2 and D10_2 all lie outwith their confidence interval, however the scale of which is minor, representing a few minutes. The modelled journey time is faster than the observed journey time data.
6.2.17 Route C14_1 along with C7_2 are examples of those journey time routes affected by additioñal schemes modēlled in TMfS: 05. The Glasgow Southern Orbital (GSO) removes traffic from the B 764 on which Route C14 travels along. Route C7 travels along the A726 which may be affected by the addition of the GSO and associated traffic flows. As a result, it would be anticipated that the modelled journey time would be outside the recorded time.
6.2.18 The modelled time to travel Route C29_1 is slower that the observed data collected for this route, however the difference is journey times is not considered to have a major affect on the performance of TMfS: 05 .

## I nter-Peak Period

6.2.19 Routes C2_1/2, C19_1, C20_1/2, C22_2, C33_1, D4_2, D5_2, D8_1 and E2_1 all lie outwith their confidence intervals, however the scale of which is minor, representing a few minutes. The modelled journey time is faster than the observed journey time data.
6.2.20 Routes C3_2, C4_1, C6_2, C18_1, C19_2, C29_1, D3_1 and E2_1 all lie outwith their confidence intervals, however the scale of which is minor, representing a few minutes. The modelled journey time is slower than the observed journey time data.

PM Peak Period
6.2.21 Routes C1_1, C2_1, C2_2, C16_1, C21_1, C27_2, D3_2, D5_2, D7_1/2, D8_1/2, D9_2 and D10_1/2 all lie outwith their confidence intervals, however the scāle of which is minor, representing a few minutes. The modelled journey time is faster than the observed journey time data. In particular, Route D10_1/2 follows a very similar pattern to the TMfS:02 comparison between modelled and observed journey time. In any instance where the journey time is outwith its confidence levels, it differs by $\pm 5$ minutes.
6.2.22 Routes C3_2, C18_1 and D11_1 all lie outwith their confidence intervals, however the scale $\overline{\text { of }}$ which is minor, $\overline{\text { representing }}$ a few minutes. The modelled journey time is slower than the observed journey time data.
6.2.23 For the Aberdeen Area Journey Times, there are no instances where a modelled journey time lies outwith its $95 \%$ confidence intervals over all three time periods.
6.2.24 For the Inter Urban Journey Times there are a total of 14 instances where a modelled journey time falls out with its $95 \%$ confidence intervals. Table 6.7 highlights the routes in question.

Table 6.7 I nter Urban J ourney Times

| Time Period | Route ID | Description | Additional Time Periods |
| :---: | :---: | :---: | :---: |
| AM | B3_2 | A9 / A811 Roundabout to A85 / A93 | IP |
|  | B9_2 | M8 J6 / A73 Roundabout to Newbridge Interchange (A8 / M9 / M8) | PM |
| IP | B4_1 | M9 J 10 / A84 to M9 J 10 | PM |
|  | B4_2 | M9 J 10 to M9 J 10 / A84 |  |
|  | B7-2 | A929 / A972 / A90 Dumbbell Roundabout (West Roundabout) to M9 Jla NB Off Slip | PM |
|  | B10_2 | A77 / B764 to A713 Whitletts Road / B749 Craigie Road |  |
| PM | B3_1 | A85 / A93 to A9 / A811 Roundabout |  |
|  | B6-2 | M90 / A9 / A93 Roundabout to A985 / A876 |  |
|  | B7_1 | M9 Jla NB Off Slip to A929 / A972 / A90 Dumbbell Roundabout (West Roundabout) |  |

6.2.25 The AM peak period has two journey time routes that lie outwith their confidence intervals. Route B3_2 is marginally outwith its confidence interval, represents a few minutes difference. The modelled journey time is slower than the observed journey time data, a similar pattern can be seen in the Inter-Peak period. Route B9_2, is faster that the observed journey time however, it must be noted that the confidence intervals for achieving validation of this journey time are very small and for a strategic model such as TMfS:05 it is very difficult to match this journey time.
6.2.26 The Inter-Peak's Route B4_1 and B4_2 both lie outwith their confidence intervals, with the modelled journey time being slower than the observed journey time. These routes are also outwith their confidence intervals in the PM Peak, in this instance the modelled journey time is marginally faster than observed data. It must be noted that Route B4_1 and its reverse B4_2, are affected by new schemes modelled in TMfS:05. The A876 Kincardine Bridge Eastern Link removes the need for traffic travelling through the village of Kincardine, therefore it can be anticipated that the modelled journey time will be different to the observed time.
6.2.27 Route 7_2 and $10 \_2$ complete the list of journey time that are not within the confidence intervals. Route 7_2's modelled journey time is faster than observed timings, it must be noted that the observed data comes from the CSTCS model (circa 2000). Despite being outwith its confidence intervals, it is envisaged that this journey time will not have a detrimental effect on the validation of TMfS: 05 . Route $10 \_2$ is slightly slower that the observed journey time however, it must be noted that the confidence intervals for achieving validation of this journey time is very small and for TMfS:05 this is very difficult to match and, given age of data, perhaps inappropriate to closely match.
6.2.28 Routes B3_1, B4_1/2, B6_2, B7_2 and B9_2 in the PM Peak Period all lie outwith their confidence intervals, however the scale of which is minor, representing a few minutes. The modelled journey time is faster than the observed journey time data. Route B7_1 remains virtually unchanged from TMFS:02 where it was marginally outside its $95 \%$ confidence intervals, its modelled journey time is slower than the observed data.
6.2.29 As the Inter Urban Routes are surveyed over longer distances, additional analysis was undertaken where these routes were divided into segments. Table 6.8 details these segments with the diagrams and results shown in Appendix I. Overall, the journey time segments show as good a level of validation as exhibited over the whole route.

Table 6.8 I nter Urban Route segments

| Route | Segment | Description |
| :--- | :--- | :--- |
| B3 | 1 | A912/A989 - A9/M90 Roundabout |

### 6.3 Validation Count Sites

6.3.1 Traffic count data not used in calibration has been used for the purposes of the validation. In total, 1,372 one-way counts have been used to present the validation of the HAM. The locations of these sites are described in Appendix J along with the source, type and date of the associated count. Figure 6.5 provides an illustration of the independent validation counts within the TMfS study area.
6.3.2 Appendix K presents tables for the AM peak, Inter-Peak and PM peak observed and modelled flows. The GEH statistic has again been used to assess the overall acceptability of the results.
6.3.3 Table 6.9 presents a summary of the validation site analysis:

Table 6.9 Validation Site Analysis

|  | $\%$ of sites with GEH value (TMfS: 02 Values in brackets) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ | $\leq 10$ | $\leq 12$ | $\leq 15$ |
| AM | $48(55)$ | $65(70)$ | $84(87)$ | $92(94)$ | $98(98)$ |
| IP | $60(62)$ | $77(76)$ | $91(90)$ | $97(96)$ | $100(99)$ |
| PM | $50(52)$ | $65(68)$ | $84(83)$ | $93(92)$ | $99(98)$ |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |

6.3.4 As with the link flow analysis performed on the calibration sites the majority of sites exhibit a GEH statistic less than 12. However, the highest GEH values are
15.9 in the AM peak, 15.7 in the Inter-Peak and 15.9 in the PM peak respectively. Appendix L contains graphical representations of the screenline results. Although the percentages are lower than TMfS: 02 values, it must be remembered that there has been a significant increase in the number of screenlines used in the validation process. Many of these additional counts are in rural areas or on the periphery of the modelled area and can be affected by a lack of adequate travel pattern data, low levels of good quality calibration data and lack intra-zonal trips. Of all the Key Links with a GEH in excess of 15 , there are 23 in the AM peak, 7 in the Inter-Peak and 21 in the PM peak.

### 6.4 Trip Length Distribution Analysis

6.4.1 Trip Length Distribution analysis has also been undertaken for each vehicle class. Appendix M contains the trip length distributions for 'Car In Work', ‘Car Non Work', 'LGV' and 'HGV' for the AM peak, Inter-Peak and PM peak respectively.
6.4.2 For each graph there are two trip length distributions shown. The first is the TMfS Prior matrix (Prior). The second is the Final TMfS assignment matrix after matrix estimation (Estimated).
6.4.3 The matrix estimation process has produced a slight increase in short distance trips in comparison to the prior matrices. This can be expected from simple matrix estimation techniques, as MVESTM adds in a small number of short distance trips particularly to match calibration screenline counts, especially those with a higher assigned confidence level. This slight increase is not deemed to reduce the quality of the calibrated matrix.

### 6.5 HGV Screenline Analysis

6.5.1 HGV Screenline Analysis has also been undertaken for the screenlines used in the validation where suitable classified vehicle count data was available.
6.5.2 Table 6.10 presents a summary of the HGV screenline analysis:

Table 6.10 HGV Screenline Analysis

|  | $\%$ of sites with GEH value (TMfS:02 values in brackets) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ | $\leq 10$ | $\leq 12$ | $\leq 15$ |
| AM | $54(62)$ | $68(77)$ | $82(88)$ | $88(92)$ | $93(96)$ |
| IP | $57(67)$ | $70(71)$ | $85(90)$ | $91(93)$ | $96(97)$ |
| PM | $59(67)$ | $73(80)$ | $88(90)$ | $94(95)$ | $97(97)$ |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |

6.5.3 The majority of HGV screenlines exhibit a GEH statistic of less than 12. The highest GEH value in the AM peak is 25.9 , with corresponding figures of 27.4 and 32.1 for the Inter-Peak and PM peak periods respectively. The TMfS:05 statistics are poorer than their TMFS:02 counterparts as a consequence of issues raised in section 6.3.4 above. It should also be stressed that no specific calibration work is carried out on HGVs, only on total PCUs and so all HGV data is used for validation. For all of the Key Links with a GEH statistic greater than 15, there are 91 in the AM peak, 59 in the Inter-Peak and 35 in the PM peak.
6.5.4 The majority of sites exhibit a GEH statistic of less than 12. As previously mentioned, the number of screenline sites used in the validation process has significantly increased with many of these additional counts being in rural areas or on the periphery of the modelled area, which can be affected by a lack of intrazonal trips.
6.5.5 Appendix N contains graphical representations of TMfS:05 screenline results, showing counts versus modelled flow in vehicles. This shows that TMfS contains a good match for most HGV counts, however, the model underestimates some links with high HGV flows.

### 6.6 Car In Work, Car Non Work Analysis

6.6.1 Screenline analysis was also conducted for those sites where a count was available for both the 'Car In Work' and 'Car Non Work' journey purposes, these were from RSI sites where trip purpose had been one of the questions. Tables 6.11 and 6.12 show the screenline analysis for 'Car In Work' and 'Car Non Work' respectively.

Table 6.11 Car In Work Screenline Analysis

|  | \% of sites with GEH value (TMFS:02 values in brackets) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ |  |  | $\leq 10$ |
| AM | $74(76)$ | $86(90)$ | $93(98)$ | $\leq 12$ | $\leq 15$ |
| IP | $78(84)$ | $91(97)$ | $98(99)$ | $98(99)$ | $100(100)$ |
| PM | $80(80)$ | $88(93)$ | $95(98)$ | $98(100)$ | $99(100)$ |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |

6.6.2 The majority of sites exhibit a GEH statistic less than 12.

Table 6.12 Car Non Work Screenline Analysis

|  | \% of sites with GEH value (TMfS:02 values in brackets) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Time Period | $\leq 5$ | $\leq 7$ | $\leq 10$ | $\leq 12$ | $\leq 15$ |
| AM | $61(56)$ | $74(73)$ | $86(89)$ | $91(95)$ | $95(98)$ |
| IP | $67(66)$ | $81(84)$ | $95(94)$ | $97(97)$ | $98(100)$ |
| PM | $53(57)$ | $66(71)$ | $83(87)$ | $88(95)$ | $93(99)$ |
| Target | $60 \%$ | $80 \%$ | $95 \%$ | $100 \%$ |  |

6.6.3 The majority of sites exhibit a GEH statistic less than 12.
6.6.4 Both the 'Car In Work' and 'Car Non Work' screenline analysis compare favourably with TMfS: 02 results.
6.6.5 In a similar comparison to the HGV validation, it should be noted that Total PCUs are used in calibration and therefore all data relating to the In Work and Non Work split is used in validation. The resulting analysis is not generally valid to compare to screenline based targets, but more so demonstrative of the validation a combination of matrix splitting (into In Work and Non Work) and the assignment methodology.

### 6.7 Census Travel to Work Data

6.7.1 The post MVESTM TMfS:05 AM peak hour matrix has been validated against 'Census Travel-to-Work' data. Table 6.13 shows the pattern, as a percentage of the total, of productions and attractions in both TMfS:05 and in the 'Census Travel-to-Work' AM peak hour matrices.
6.7.2 TMfS: 05 tends to have slightly high proportions in the urban areas and much smaller proportions in the more rural areas. This is because within urban areas, TMFS has a fine zoning system, rural areas however, have a coarse zoning system. In these local authorities, the only trips in the model are long distance trips and intra zonal trips are not included.
6.7.3 The table shows that the pattern within the base AM peak TMFS:05 matrix demonstrates a good match with the Census Travel-to-Work matrix.

Table 6.13 Production and Attraction patterns as a percentage of the total

| Local Authority | census productions | TMfS: 05 productions | census attractions | TMfS: 05 attractions |
| :---: | :---: | :---: | :---: | :---: |
| Aberdeenshire | 4\% | 3\% | 2\% | 1\% |
| Angus | 2\% | 1\% | 1\% | 1\% |
| Argyll \& Bute | 0\% | 0\% | 0\% | 0\% |
| City of Aberdeen | 5\% | 7\% | 8\% | 9\% |
| City of Dundee | 3\% | 2\% | 4\% | 2\% |
| City of Edinburgh | 11\% | 13\% | 14\% | 15\% |
| City of Glasgow | 10\% | 18\% | 16\% | 23\% |
| Clackmannanshire | 1\% | 1\% | 1\% | 1\% |
| Dumfries \& Galloway | 2\% | 2\% | 2\% | 2\% |
| East Ayrshire | 3\% | 1\% | 2\% | 1\% |
| East Dunbartonshire | 4\% | 4\% | 2\% | 2\% |
| East Lothian | 2\% | 1\% | 1\% | 1\% |
| East Renfrewshire | 3\% | 4\% | 1\% | 2\% |
| England \& Wales | 0\% | 0\% | 0\% | 0\% |
| Falkirk | 4\% | 3\% | 3\% | 2\% |
| Fife | 8\% | 9\% | 7\% | 8\% |
| Highland | 0\% | 0\% | 0\% | 0\% |
| Inverclyde | 2\% | 0\% | 2\% | 1\% |
| Midlothian | 2\% | 1\% | 1\% | 1\% |
| Moray | 0\% | 0\% | 0\% | 0\% |
| North Ayrshire | 3\% | 1\% | 2\% | 1\% |
| North Lanarkshire | 7\% | 7\% | 6\% | 6\% |
| Perthshire \& Kinross | 3\% | 2\% | 3\% | 1\% |
| Renfrewshire | 4\% | 5\% | 5\% | 5\% |
| South Ayrshire | 3\% | 1\% | 3\% | 1\% |
| South Lanarkshire | 7\% | 6\% | 6\% | 5\% |
| Stirling | 2\% | 2\% | 2\% | 2\% |
| The Borders | 1\% | 1\% | 1\% | 1\% |
| West Dunbartonshire | 2\% | 1\% | 1\% | 1\% |
| West Lothian | 4\% | 2\% | 4\% | 2\% |

6.7.4 Appendix $P$ contains similar analysis to Table 6.10, although the data in the appendix is presented in terms of the pattern of trips produced by each Local Authority. For each Local Authority, the AM peak trip pattern to each of the other Local Authorities demonstrates a good match to the Census Travel-to-Work data. This data is also shown with the exclusion of intra Local Authority Trips. This shows an even better match, for all local authorities except those, right on the model periphery.
6.7.5 It should be noted, however, that the TMfS commuter matrix was extracted from the Base Year Non-Work matrix using factors from the Scottish Household Survey. These factors are only at a three sector level (Edinburgh, Glasgow and elsewhere) and hence the analysis is very coarse.. It should, also be noted that the factors tend to be higher in the Glasgow and Strathclyde area.

### 7.1 Conclusions

7.1.1 This report has presented the calibration and validation of the 2005 TMfS Rebase Highway Assignment Model.
7.1.2 The network was developed from the TMfS: 02 with numerous schemes added to the network. A checking procedure was undertaken on all approaches to modelled junctions in order to verify the link distances and capacity indices.
7.1.3 The zone system was altered to include the creation of new zones at Aberdeen, Prestwick and Edinburgh Airports as well as at the Royal Bank of Scotland (RBS) headquarters on the A8. Adjustments were also made to those zones that had irregular trip rates, based on the latest 2005 TELMoS planning data. Before applying MVESTM, the demand matrices were passed through the Park and Ride procedure.
7.1.4 An exacting calibration has been undertaken to link/screenline counts. The model is particularly well calibrated in the key areas (trunk roads/motorways), it validates well in the vast majority of the modelled area. Whilst it is less well calibrated in some rural areas, due to the large zones on the periphery of the modelled area and absence of quality observed data, the model still meets good standards of calibration. It should also be considered that TMfS:05 model incorporates a significantly higher number of screenlines and counts both in the calibration and validation process than that included in TMfS:02.
7.1.5 The model validates well in the key areas against journey times and against the very large number of counts not included in calibration. TMfS: 05 also incorporates an increased number of journey times for the validation process over that used in TMfS: 02.
7.1.6 Our view is that the HAM has been successfully developed and is fit for its intended purpose.
7.1.7 The TMfS: 05 Highway Assignment Model can be used for the assessment of major strategic Highway schemes and policy decisions as part of the TMfS modelling suite. It is also fit for use as a source of travel demand and network structure for more localised models.

### 7.2 Recommendations

7.2.1 For future development, it is recommended that the highway matrices are enhanced using new RSI data. In particular, the collection of RSI data within Edinburgh is particularly dated and the model would benefit from inclusion of updated information.
7.2.2 We also recommend that the project of turning links which should be dualled from two-lane one-way links into fully dualled links is completed, this task will be specifically useful in any congestion/environmental mapping that may be undertaken as part of future work streams.
7.2.3 Each potential application of the model should be assessed in detail prior to ensure that the quality of the model is appropriate for the desired output as the quality of data input and consequently output differs across the entire modelled area.
